

Antibiotic resistance

- Secondary Care: Facts and figures

Fact 1. Antibiotics remain an invaluable but finite resource. They have contributed to the reduction in mortality and morbidity from infectious disease and have made other treatments and procedures such as cancer treatments and organ transplantation possible.

Whilst the number of infections due to antibiotic-resistant bacteria is growing, the pipeline for new antibiotics is discouraging.

It is important to preserve antibiotics, in particular carbapenems (imipenem, meropenem, ertapenem and doripenem) which are invaluable for the treatment of infections due to multi-resistant gram negative bacteria, including extended β -lactamases.

Carbapenem-resistant Enterobacteriaceae remain an emerging threat (Figure 1)

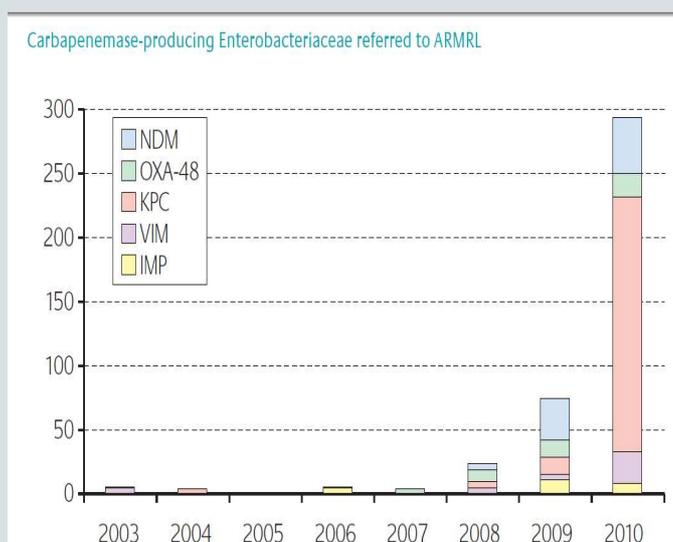

Figure 1: Carbapenemase-producing Enterobacteriaceae referred to Antibiotic Resistance Monitoring & Reference Laboratory, Health Protection Agency, England
http://www.hpa.org.uk/web/HPAwebFile/HPAweb_C/1294740725984

Fact 2. Antibiotic resistance is an increasingly serious patient safety and public health problem in Europe and the world

The emergence, spread and selection of antibiotic-resistant bacteria is a threat to patient safety in hospitals^{1, 2} because:

- Infections with antibiotic-resistant bacteria result in increased patient morbidity and mortality, increased hospital length of stay and costs.⁴⁻⁵

- Antibiotic resistance frequently leads to a delay in appropriate active antibiotic therapy⁶
- Inappropriate or delayed antibiotic therapy in patients with severe infections leads to worse patient outcomes and sometimes death⁷⁻⁹.

Fact 3. Misuse of antibiotics in hospitals is one of the main factors driving antibiotic resistance

Patients who are hospitalised have a high probability of receiving an antibiotic¹⁰ and 50% of all antibiotic use in hospitals may be inappropriate¹¹. Misuse of antibiotics in hospitals is one of the main factors driving development of antibiotic resistance¹²⁻¹⁴.

Misuse of antibiotics include¹⁵:

- Delaying antibiotic treatment in critically ill patients;
- Prescribing antibiotics unnecessarily
- Using broad-spectrum antibiotics too generously, or narrow-spectrum antibiotics incorrectly;
- Using lower or higher antibiotic dose than appropriate for the specific patient;
- Inappropriate duration of antibiotic treatment - too short or too long
- Not modifying antibiotic treatment according to microbiological culture data results.
- Omitting or delaying doses of prescribed antibiotics

Fact 4. Benefits of prudent antibiotic use

Prudent use of antibiotics can prevent the emergence and selection of antibiotic-resistant bacteria^{2, 14, 16-18}. Decreasing antibiotic use has been shown to result in lower incidence of antibiotic resistant bacteria and *Clostridium difficile* infections^{1, 2, 16, 19} (Figures 2 and 3 overleaf).

Antibiotic resistance

- Secondary Care: Facts and figures

Fact 5. Multifaceted strategies can result in prudent antibiotic use

Multifaceted strategies to promote prudent use of antibiotics (Antimicrobial Stewardship) include: ^{2, 16, 20, 21, 22-25}

- Adherence to national antimicrobial stewardship guidance^{2, 25};
- Ongoing and repeated education of prescribers and specialists²;
- Adherence to evidence-based local hospital antibiotic guidelines and policies^{2, 16, 20};
- Monitoring of hospital antibiotic resistance and antibiotic use data to guide empiric antibiotic therapy in severely ill patients²¹;
- Administering antibiotic prophylaxis for surgery following guidelines on the correct timing and optimal duration²²;
- For some indications, using shorter rather than longer duration of treatment^{12, 23-24};
- Ensuring strategies are in place to prevent delayed doses of antibiotics or patients missing doses
- Taking microbiological samples before initiating empiric antibiotic therapy, monitoring culture results and streamlining antibiotic treatment based on the culture results²⁵.
- Consult with infectious diseases physicians, microbiologists and pharmacists in your decisions about antibiotic therapy for patients^{2, 16, 20}

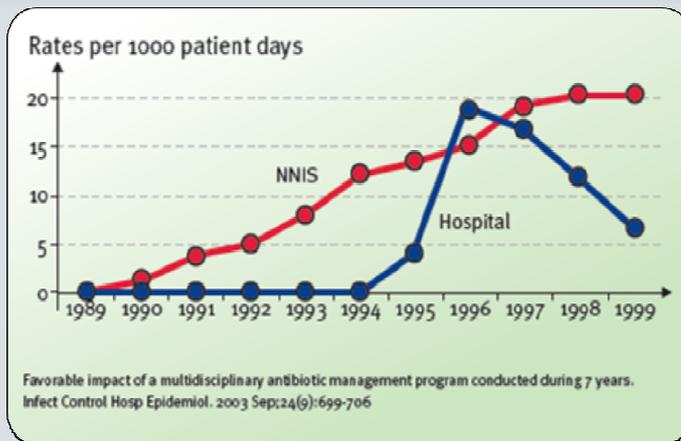

Figure 2. Rates of Vancomycin-resistant *Enterococci* in hospital before and after implementation of the antibiotic management program compared with rates in National Nosocomial Infections Surveillance (NNIS) System* hospitals of similar size. Source: Carling P, et al 2003¹⁶.

*NNIS is now the National Healthcare Safety Network (NHSN).

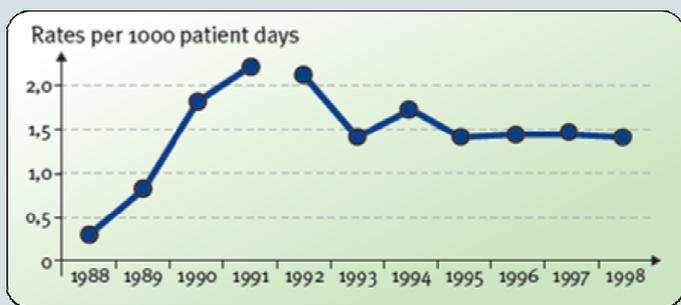

Figure 3. Rates of nosocomial *Clostridium difficile*, expressed per 1,000 patient-days, before and after implementation of the antibiotic management program. Source: Carling P, et al 2003¹⁶.
