Disease Control Strategy for African and Classical Swine Fever in Great Britain

August 2014
Swine Fever Disease Control Strategy (ASF and CSF)

1 Background ......................................................................................................... 6
  1.1 Purpose of document .................................................................................... 6
  1.2 Strategic fit .................................................................................................... 6
  1.3 African Swine Fever (ASF) and Classical Swine Fever (CSF) ...................... 7

2 Strategic control framework ................................................................................. 9
  2.1 Disease management principles ................................................................... 9
  2.2 Disease control objective .............................................................................. 9
  2.3 Approach to disease control ......................................................................... 9
  2.4 Outbreak dynamics and veterinary response .............................................. 10
  2.5 Decision Making – roles and organisational structures ............................... 12

3 Maintaining Disease Freedom and Surveillance ................................................ 13
  3.1 Introduction ................................................................................................. 13
  3.2 International Surveillance ............................................................................ 13
  3.3 Trade / imports ............................................................................................ 13
  3.4 Control of ASF and CSF pathogens ............................................................ 14
  3.5 Controls to stop disease entering the domestic pig population ................... 14
  3.6 Pigs living in the wild ................................................................................... 15
  3.7 Disease suspicion and reporting ................................................................. 16
  3.8 Surveillance .................................................................................................. 16
  3.9 Raising stakeholder awareness .................................................................. 17

4 Suspicion of disease in GB ................................................................................ 18
  4.1 Suspicion of swine fever – requirement to notify ......................................... 18
  4.2 Actions at premises where disease is suspected ........................................ 18
  4.3 Contact premises ........................................................................................ 19
  4.4 Killing of pigs at suspect and dangerous contact premises ....................... 20
  4.5 Diagnostic investigation .............................................................................. 21
  4.6 Epidemiological assessment ....................................................................... 21
  4.7 Optional controls in the area around a suspect premises ........................... 21
  4.8 Suspicion of swine fever in pigs living in the wild ........................................ 22
  4.9 Outcome of investigation ............................................................................ 22
  4.10 Communication ........................................................................................... 23

5 Confirmation of ASF or CSF in GB .................................................................... 24
  5.1 Confirming a case of swine fever ................................................................. 24
  5.2 International notification obligations ............................................................ 24
  5.3 Trade and safeguard measures .................................................................... 24
  5.4 Disease control measures .......................................................................... 25
  5.5 Controls outside protection and surveillance zones .................................... 25
  5.6 Cross-border zones ..................................................................................... 25
  5.7 Communications and raising stakeholder awareness .................................. 25

6 Controls at infected premises ............................................................................ 27
  6.1 Definition of an infected premises ............................................................... 27
  6.2 Movement and access controls at IP ............................................................ 27
  6.3 Killing of pigs at an IP .................................................................................. 27
  6.4 Destruction of semen, ova and embryos ..................................................... 28
  6.5 Cleansing and disinfection (C&D) ............................................................... 28
  6.6 Tracing of meat from animals slaughtered in risk period .......................... 29
  6.7 For ASF only - Measures when tick vectors are suspected or confirmed at an IP 29
6.8 Compensation ........................................................................................................ 30
6.9 Repopulation of infected premises .................................................................... 30
6.10 Repopulation of ASF-infected premises where the occurrence of disease has been linked to soft tick vectors ................................................................. 31
6.11 Communications ............................................................................................... 32

7 Measures in Disease Control Zones .................................................................. 33
7.1 Disease control zone definitions – temporary control zone ............................ 33
7.2 Disease control zone definitions – protection and surveillance zone .......... 33
7.3 Disease control zone definitions – restriction zone ........................................... 33
7.4 Impact of multiple control zones ..................................................................... 34
7.5 Disease control zone definitions – Feral pig zones ........................................ 35
7.6 Disease control zone definitions – vaccination zone ....................................... 35
7.7 Movement prohibitions and derogations in control zones ............................. 35
7.8 Movement restrictions and licences – live pigs ............................................... 36
7.9 Movement restrictions and licences – other (non-porcine) animals .............. 38
7.10 Movement restrictions and licences – genetic material ............................... 38
7.11 Movement restrictions and licences – carcases, pig products and waste .... 38
7.12 Movement restrictions and licences – vehicles ............................................. 38
7.13 Movement restrictions and licences – feed ..................................................... 39
7.14 Biosecurity at pig premises ........................................................................... 39
7.15 Surveillance and epidemiological investigations ......................................... 39
7.16 Communications ............................................................................................. 40
7.17 Impact of controls .......................................................................................... 40

8 Special cases – establishments and animal gatherings ...................................... 42
8.1 Disease at establishments, animal gatherings and during transport ............ 42
8.2 Suspicion of swine fever in pigs at an establishment ..................................... 42
8.3 Confirmation of swine fever at an establishment .............................................. 43
8.4 Suspicion of swine fever at an animal gathering .......................................... 43
8.5 Confirmation of swine fever at an animal gathering ....................................... 44
8.6 Suspicion and confirmation of swine fever during transportation ............... 44
8.7 Communications when suspicion of swine fever at an establishment or gathering ........................................................................................................... 45
8.8 Control of establishments in protection and surveillance zones .................. 45
8.9 Control of animal gatherings in protection and surveillance zones .............. 46

9 Breeds at risk and other specialist pigs .............................................................. 48
9.1 Defining breeds at risk and other specialist pigs ........................................... 48
9.2 Responsibilities when swine fever is not present ........................................ 48
9.3 General measures during a swine fever outbreak ........................................ 48
9.4 Premises in control zones ......................................................................... 49
9.5 Dangerous contact premises ......................................................................... 49
9.6 Suspicion of swine fever ............................................................................... 49
9.7 Confirmation of swine fever .......................................................................... 50

13 Glossary/Acronyms ............................................................................................ 62
1 Background

1.1 Purpose of document

1.1.1 This document describes how government and others would manage an outbreak of either African swine fever (ASF) or Classical swine fever (CSF) in Great Britain (GB). In this document, reference to ASF or CSF is intended to refer to the specific disease. Where the collective term “swine fever” is used it is intended to refer to both ASF and CSF.

1.1.2 Swine fever can spread throughout GB and will not be halted by a simple administrative boundary. Therefore, in managing a swine fever outbreak the strategy seeks complementary, consistent and coordinated measures in all regions of GB. This strategy is endorsed by Defra, Scottish Government and the Welsh Government (hereafter referred to as government), although responsibility for management of an outbreak in respective regions falls to the respective governments.

1.1.3 This strategy was prepared in consultation with delivery agents, veterinary experts and organisations representing pig producers and processors. This document is intended to provide a context to the prevention of swine fever outbreaks and a clear explanation of how the law\(^1\) will be applied in the event that swine fever is suspected or confirmed in GB.

1.1.4 The strategy will therefore help all parties that might be affected by an outbreak of swine fever to consider how they can be better prepared to respond quickly to an outbreak of swine fever and to identify the measures they might take to mitigate the potential impact of these control measures.

1.1.5 The document structure is:

- Section 2 explains the broad disease control framework
- Section 3 gives an overview of the measures currently adopted to reduce the likelihood of swine fever entering GB
- The main focus of this document (sections 4 to 11) is on the disease control measures to be taken once disease is detected
- Section 12 outlines the action taken to allow normal business operation to be re-established once an outbreak has been controlled and swine fever eradicated

1.2 Strategic fit

1.2.1 The strategy is consistent with broad animal health policies including:

- prevention is better than cure

\(^1\) The Diseases of Swine Regulations 2014
• sharing responsibility and cost, requiring close working between government and industry in developing and delivering disease controls
• Complying with the World Health Organisation for Animal Health (OIE - Office International des Epizooties) disease control chapters
• implementing European Union (EU) law and international obligations to trading partners
• mitigating the risk of spread of disease to other member states (MSs) or third countries
• ensuring the welfare of animals
• being consistent with wildlife management policies
• applying disease response plans set out in the GB governments’ exotic disease contingency plans (Defra’s Contingency Plan for Exotic Animal Diseases; the Welsh Government Contingency Plan for Exotic Animal Diseases; Scotland’s Exotic Animal Disease Contingency Framework Plan and the Great Britain and Northern Ireland Contingency Plan for Exotic Notifiable Diseases of Animals)

1.3 African Swine Fever (ASF) and Classical Swine Fever (CSF)

1.3.1 The CSF and ASF virus are not known to have any health impact for people, thus the measures in this strategy are concerned only with animal health. These viruses produce similar clinical signs and impact on pig health. They are however caused by different viruses with different incubation periods and different underlying science. The steps to control both diseases are very similar.

1.3.2 ASF has never been detected in the United Kingdom (UK). CSF was eradicated from GB in 1966, with occasional outbreaks subsequently being contained and eradicated. The last UK outbreak occurred in 2000 when 16 farms were affected and around 75,000 pigs culled for disease control purposes with compensation of around £4.4 million paid for animals slaughtered.

1.3.3 ASF and CSF can be spread through:
• Direct contact with infected pigs, faeces, genetic material or body fluids
• Indirect contact via fomites such as equipment, vehicles or people who work with pigs moving between pig farms with ineffective biosecurity
• Pigs eating infected pig meat or meat products. Both ASF and CSF virus can survive in meat and pig products for several years

1.3.4 Aerosol routes are not thought to be a major mechanism of spread for CSF or ASF although these have been shown to occur experimentally.

1.3.5 It is possible that ASF or CSF can be spread over short distances via mechanical vectors.

1.3.6 In addition, ASF can be spread by biological vectors, in particular ticks of the species Ornithodoros. At the present time evidence suggests there are no
known competent vectors for ASF in the UK.

1.3.7 Offspring of CSF-infected sows can become infected in the uterus and can shed the virus for months after birth.

1.3.8 ASF and CSF can occur in acute, chronic and mild forms. The acute form can cause severe disease from which the majority of affected pigs die.

1.3.9 The clinical signs of CSF are very similar to ASF and the two diseases can only be differentiated by diagnostic tests.
2 Strategic control framework

2.1 Disease management principles

2.1.1 Managing exotic diseases is primarily concerned with managing risk. By definition exotic diseases are not normally present in GB and therefore we can manage the risks in two ways:

- taking day-to-day measures to reduce the likelihood of an outbreak of swine fever in GB by implementing practices to prevent its entry and to detect it quickly if swine fever should enter GB
- being prepared to act quickly to reduce the impact of an incursion of swine fever once it is detected in GB

2.2 Disease control objective

2.2.1 If swine fever is detected in GB the key objective is to:
- contain and eradicate any incursion into domestic pigs

2.2.2 Secondary objectives include to:
- prevent the exchange of swine fever virus between pigs living in the wild and domestic pigs
- contain and eradicate any incursion of swine fever into pigs living in the wild

2.2.3 It is inevitable that the controls necessary to stop spread and eradicate swine fever will have an impact on day-to-day business practices. However, these disease control measures seek to:
- minimise the number and duration of premises affected
- minimise the number of pigs culled
- protect the welfare of healthy pigs
- minimise any impact on pig producers, meat processors and other related industries and to domestic and international trade in pigs and pig products
- minimise the impact on tourism, the environment and rural and wider economies
- support sustainability within industry
- minimise the burden on taxpayers
- comply with international obligations to control an outbreak of ASF or CSF

2.3 Approach to disease control

2.3.1 The approach to disease control is to:
- detect clinical signs suggestive of swine fever early and to report rapidly, to enable diagnosis as soon as possible after swine fever enters GB. This will limit the extent of spread of swine fever that can occur before disease controls are brought into force, thereby reducing the initial size of the outbreak
• contain swine fever at premises where it is detected, and eradicate it swiftly and effectively such that it cannot be re-introduced
• limit risk of any further spread of swine fever from premises connected with or in the vicinity of the infected premises
• undertake risk assessments before easing restrictions and undertaking surveillance for signs of further disease before lifting restrictions
• comply with European Union law and international trade obligations under the World Organisation for Animal Health (the OIE) disease control codes

2.4 Outbreak dynamics and veterinary response

2.4.1 If swine fever enters GB and is not detected at the point of entry (detection in live pigs is unlikely as only healthy animals should be exported) there will be a period between entry and when swine fever is detected. During this phase the silent spread of swine fever is a significant factor in the eventual size of an outbreak.

2.4.2 Adopting good practice at all times will limit the extent of spread in this period. Measures include: careful sourcing of pigs; adopting effective movement standstills; quarantine; herd-health vigilance; good record-keeping and high standards of biosecurity. It is particularly important to comply with rules prohibiting the feeding of swill, catering waste or other animal products to pigs. Taking these steps greatly reduces the likelihood of a large outbreak.

2.4.3 Anyone who suspects swine fever is required to notify the Animal Health Veterinary Laboratories Agency (AHVLA\(^2\)). Initial suspicion will primarily rely upon the vigilance of pig keepers and correct veterinary diagnosis against other similar diseases. The biology of the specific swine fever virus and type of pigs involved will affect the degree of clinical signs displayed. Given the potential similarity of swine fever symptoms to other endemic diseases of pigs there is concern a mild form of swine fever could go unnoticed for some months. It is therefore important that pig keepers and vets consider whether swine fever is a potential diagnosis.

2.4.4 Once notified, AHVLA will investigate and as necessary take samples for laboratory analysis; test results are available within 24-48 hours. Whilst under investigation the premises is placed under restrictions to prevent the further spread of swine fever. Government may also impose a temporary control zone around the suspect premises. The investigation will either negate the presence of swine fever or will lead to the Chief Veterinary Officer (CVO) confirming either CSF or ASF.

2.4.5 The consequential impact of declaring the first case of swine fever disease in GB is significant. The UK international trade status in pigs and pig products is affected and restrictions will be placed on some or all domestic pig businesses. Government and industry incur costs both to respond to the

\(^2\) AHVLA will become part of the combined Animal and Plant Health Agency from 1 October 2014
outbreak and in terms of indirect disruption to normal business operation. The process to confirm the first case of swine fever will be in line with the requirements of the relevant EU diagnostic manual. Of course, delay in formally confirming disease can lead to further disease spread and therefore during the suspicion stage the need for temporary restrictions is regularly reviewed.

2.4.6 On confirmation of swine fever, the Infected Premises (IP) will remain under restrictions and action taken to eradicate disease by killing pigs and completing full cleansing and disinfection to destroy any remaining virus. In order to reduce the risk of swine fever spreading from farms that may have been infected locally, area restrictions (protection and surveillance zones) will be put in place. Also government veterinarians will trace any potential movements of disease on or off the IP to the source/destination (contact) premises which will be placed under restrictions and investigated for signs of disease.

2.4.7 At the time swine fever is first confirmed little is likely to be known about the source of the infection, how long it has been present in GB, how it was introduced or where else it may be present. It is likely other infected premises will subsequently be identified. With such uncertainty, the main focus of government controls is to prevent the risk of further disease spread whilst epidemiological leads are followed up and the disease situation emerges in that area. Therefore in the early stages of an outbreak, including when swine fever is detected in new areas, strict controls will apply on the movement of pigs and things liable to spread disease and whilst there is uncertainty on the extent of disease spread it is unlikely movements will be licensed.

2.4.8 After a period (generally at least a few weeks from when the last new cases in the area were confirmed) confidence increases that disease has been contained. Factors affecting confidence include whether tracings of things liable to have spread disease from the IP have been completed, the incubation period of disease, and the strain of swine fever (such as mild or virulent). During this phase, government may ease some restrictions in the areas around the infected premises incrementally, taking account of veterinary risk assessments (VRAs), allowing limited but controlled activity to recommence. However, each time a new case is identified, especially if there is no clear link to existing cases, government will consider whether it needs to re-impose the stricter controls.

2.4.9 Once there are no new cases in the area and the pigs on the infected premises have been killed out and the premises adequately cleansed and disinfected, government will start considering lifting of the area restrictions. Surveillance of all premises with pigs in the area under restriction will be undertaken to ensure there are no undetected pockets of swine fever; this cannot commence before certain legal minimum time periods have passed. Once satisfied the zones are free of swine fever, and taking account of the wider disease situation, the zones will be lifted removing the area restrictions.

---

2.4.10 Once all the zones and infected premises in GB have been cleared and restrictions lifted government is able to put a case to the EU and the OIE to re-establish recognition of swine fever freedom. Whether or not feral pigs were implicated or vaccination was used will impact the actions and timescale for claiming freedom.

2.4.11 Even after this there can be a considerable tail of work:

- to re-establish third country markets
- to publish an epidemiology report into the outbreak
- to consider what lessons can be learned
- to respond to EC missions, other reports and enquiries
- for operational partners and industry to recover to their pre-outbreak position

2.4.12 If disease is suspected in pigs living in the wild (feral pigs) action will be taken to confirm or negate swine fever. If swine fever is confirmed, action will be taken to eradicate it from the feral pig population. Additional controls will apply in the area.

2.4.13 Whilst the primary control at infected premises and for swine fever in feral pigs is to cull out affected farms and populations, vaccination against CSF (only) may be authorised in limited circumstances, where it is beneficial in controlling CSF. No vaccine is currently available for ASF.

2.4.14 Subsequent sections of this strategy reflect this summary of how disease outbreaks develop and the controls available.

2.5 Decision Making – roles and organisational structures

2.5.1 This document sets out the strategy and controls to deal with an outbreak of swine fever. The related management and decision-making processes are explained in governments’ exotic disease contingency plans (see section 1.2.1).
3 Maintaining Disease Freedom and Surveillance

3.1 Introduction

3.1.1 ASF and CSF are not normally found in the UK. In order to keep swine fever out it is important to understand the routes of disease incursion and, as appropriate, to put in place countermeasures to reduce the likelihood of incursion. Resources are targeted at the countermeasures that are considered most cost effective in reducing the risk of introduction.

3.1.2 This section summarises current measures to:
- prevent incursions of swine fever into UK/GB
- minimise the likelihood of spread of swine fever within GB prior to its detection
- detect an incursion of swine fever early and activate disease contingency plans

3.2 International Surveillance

3.2.1 Defra monitors the international disease situation and publishes qualitative risk assessments and preliminary outbreak assessments\(^4\) as appropriate. These assessments are used by government to inform policy-making and measures to prevent incursion to the UK.

3.2.2 When disease is not present in the country, controls need to be proportionate to the risk. By monitoring the international situation the option to vary preventative controls is considered against changing threats. Government works closely with other agencies to deliver proportionate controls at borders.

3.3 Trade / imports

3.3.1 Government targets surveillance at the highest risk routes of incursion to check for continued freedom from swine fever.

3.3.2 EU member states are able to import and export animals and animal products to/from other EU member states and third countries. Animal and animal products imported into UK, or passing through it, must meet the conditions and pass veterinary checks under import and export regulations\(^5\) for EU and third country trade. These include documentary, identity and physical examinations. Limited samples may be taken from live pigs for laboratory analysis.

3.3.3 Where a member state or region is affected by swine fever the European Commission imposes additional controls on what may be exported from the region to other member states. These additional controls reduce the risk of

---

moving disease from member state to other member states or to third countries. These measures therefore serve to reduce the risk to the UK from swine fever affected regions. Similar trade principles reduce the risk of swine fever entering the EU from third countries affected by swine fever. The restrictions will depend on the nature of the outbreak and whether it affects domestic pigs or pigs living in the wild. These restrictions may apply to the export from swine fever-affected regions of pigs, pig semen, ova or embryos, pig products including pig meat or uncooked pig meat products and can extend to requiring pork products to be treated.

3.3.4 The UK implements enhanced import controls to protect against pigs, pork or pork products being illegally imported from affected regions, although there remains a threat from such activity.

3.4 Control of ASF and CSF pathogens

3.4.1 Movement of samples containing (or which might contain) ASF or CSF to laboratories is regulated and controlled under the Specified Animal Pathogens Order (SAPO) and Import of Animals Pathogens Order (IAPO).

3.4.2 The use of swine fever vaccine in UK is prohibited. This prohibition reduces the risk of introducing swine fever through the use of live vaccines, as well as simplifying the detection and control of disease.

3.5 Controls to stop disease entering the domestic pig population

3.5.1 If swine fever enters the pig population in GB it may take some time before the signs of disease are suspected. Minimising the period when disease is present but undetected is an important factor in minimising the eventual size of an outbreak. During this period there is a risk of rapid and uncontrolled spread within the domestic pig population or into pigs living in the wild (see below). Thus measures when swine fever is not known to be present in GB are critical to minimising the impact of an outbreak.

3.5.2 The application of good farming practice is a simple and effective way of reducing the likelihood of introducing disease to a farm and of minimising the rate of spread of undetected disease; these practices have benefit in minimising the spread of endemic disease.

3.5.3 Routes of undetected spread and relevant mitigating controls include:

- Spread through movement of infected pigs: the movement and stand-still controls limit the rate at which disease moves from farm to farm.
- Contamination of places where infected pigs are kept: this requires the cleansing and disinfection of pig pens and farms when they are depopulated.

---

6 Pigs (Records, Identification and Movement) 2011; the Pigs (Records Identification and Movement) (Scotland); the Pigs (Records, Identification and Movement) (Wales) Order 2008 & Disease Control (England) Order 2007 as amended; Disease Control (Scotland) Order 2002; Disease Control (Wales) Order 2003
(good practice), and animal gatherings (slaughterhouses, markets, and shows) where pigs from different farms mix (legal requirement7)

- Infection through infected pig products: if pigs are killed which are infected with the swine fever virus, the food product, whilst not being harmful to humans, can cause pigs to become infected if eaten. This risk is mitigated by observing the ban on feeding swill to pigs8. This also prohibits the use of pig products in pig feed. It is therefore also important to source feed from reputable suppliers and to store it in such a way to avoid contamination.

- Infection through artificial insemination (AI): pigs can be infected with swine fever through the use of semen from infected pigs. The risk of this is minimised by using semen from approved artificial insemination centres9 where controls on production of pig semen are in place which reduce the likelihood of swine fever entering the unit. Adopting similar good practice within non-approved commercial semen centres reduces risks of disease incursion to these units and thus onward spread.

- Introduction of (infected) pigs: sourcing pigs from known and reliable sources will reduce the risk of introducing infected pigs to the herd. Particular care is needed when sourcing from areas outside the UK where swine fever is known to be, or may be present. This can be further mitigated by isolating pigs and testing before mixing with the herd. Animals originating outside the UK are subject to pre-export certification and testing where appropriate.

- Fomite spread: contaminated vehicles and other things used to move infected pigs could spread disease and therefore vehicles and other equipment used in the movement of pigs must be cleansed and disinfected. Pig keepers implementing and operating good biosecurity practices at all times reduces the likelihood of disease entering premises or spreading rapidly within separate epidemiological units within the premises. This can include changing clothes and footwear, staff adopting good personal hygiene, prohibiting the eating of pork products on farm, cleansing and disinfecting at control points (such as entry to the farm and/ or between sheds), restricting the movement of vehicles on/ off farm, and controlling the disposal and collection of fallen stock and other waste.

### 3.6 Pigs living in the wild

#### 3.6.1 All pigs, including wild boar, are susceptible to swine fever regardless of whether they are kept domestically or living in the wild. When swine fever is absent from the UK, local communities and individual landowners have primary responsibility for feral boar management, including population

---

7 Animal Gatherings Order 2010, Animal Gatherings (Wales) Order 2010, the Disease Control Interim Measures (Scotland) Order 2002 (as amended) and The Markets, Sales and Lairs Order 1925 (as amended)
8 Animal By-Products (Enforcement)(England) Regulations 2013; the Animal By-Products (Enforcement)(Scotland) Regulations 2013 and Animal By-Products (Enforcement)(Wales) Regulations 2014
9 EU Directive 90/429/EC - Animal health requirements applicable to intra- Community trade in and imports of semen of domestic animals of the porcine species
control\textsuperscript{10}. Where practical, government will facilitate this regional management through the provision of advice and guidance. Government works with landowners where specific issues are identified in relation to the management of populations of pigs living in the wild.

3.6.2 In order to be ready for any outbreak of swine fever government records information on the location of feral pig populations.

3.6.3 There are various potential routes for swine fever to be introduced into feral pigs, including the consumption of infected pig products which are fed illegally or scavenged from waste bins or other sources. A veterinary risk assessment concluded that the most likely route of introduction is from infected domestic pigs\textsuperscript{11}. The risk of swine fever being introduced to pigs living in the wild is mitigated by maintaining general policies for management of wildlife, enforcing rules on feeding of animal by-products and as far as practicable minimising the scope for contact between pigs living in the wild and domestic pig holdings.

3.7 Disease suspicion and reporting

3.7.1 ASF and CSF are notifiable diseases. This means if anyone suspects swine fever in a pig or pig carcase they must report it to their local AHVLA office.

3.7.2 Monitoring the health of pig herds and being vigilant for signs of disease is an important element in speeding up the detection of disease and thereby minimising the size of outbreaks.

3.7.3 The primary method for detecting disease incursions onto farms early is through best practice animal husbandry, through pig-keepers’ observation of behaviours and signs in the herd, and as part of a herd-health plan. Farmers are expected to consult their veterinarians where they see clinical signs or changes in behaviour or other health indicators; veterinarians will consider whether swine fever should be considered as a potential diagnosis. There are several endemic diseases affecting pigs which have similar signs and symptoms to swine fever and this has the potential to lead to swine fever not initially being considered, thus delaying reporting.

3.8 Surveillance

3.8.1 Further surveillance for swine fever is carried out to provide assurance of continued disease freedom in GB. This surveillance includes:

• Official investigation of reports of suspicion of swine fever in pigs (domestic and living in the wild) including submission and testing of samples as necessary. This is supported by a number of other scanning surveillance activities, including:
  o veterinary assessment and diagnostic investigations into outbreaks of clinical disease by trained veterinary investigators on samples and carcases submitted to veterinary laboratories
  o ante-mortem and post-mortem inspections of animals/carcases in abattoirs and game handling establishments for signs of disease by Food Standards Agency (FSA) official veterinarians (OV)

• assistance of private veterinary practitioners attending pig farms during their clinical and routine visits advising on pig health issues and as part of farm assurance schemes sero-surveillance of boars for CSF (not ASF) entering and resident at EU-approved Artificial Insemination (AI) Centres licensed for export of semen\(^\text{12}\)
• serological testing for CSF of certain pigs for export

3.9 **Raising stakeholder awareness**

3.9.1 Biosecurity advice is made available to pig keepers by GB Governments including information on typical clinical signs of ASF and CSF.

3.9.2 There is continuing publicity on the risk of illegally feeding waste food to pigs.

3.9.3 Private veterinary surgeons are an important source of advice to pig keepers.

\(^{12}\) Directive 90/429/EEC - Animal health requirements applicable to intra-Community trade in and imports of semen of domestic animals of the porcine species
4 Suspicion of disease in GB

4.1 Suspicion of swine fever – requirement to notify

4.1.1 ASF and CSF are notifiable diseases. This means if anyone suspects swine fever in a pig or pig carcase they must report it to their local AHVLA office. Any person who examines a sample taken from a pig or carcase and who suspects the pig/carcase is infected with swine fever virus or who detects antibodies to, or antigens of, that virus must immediately notify their local AHVLA office. If unsure whether to notify disease they may seek a consultation with an AHVLA vet.

4.1.2 The duty vet at the AHVLA office will liaise with AHVLA vets with responsibility for notifiable disease reporting and, if disease cannot be negated remotely, will arrange for an AHVLA Veterinary Inspector (VI) to visit the premises. Information about the case is shared with relevant government units via a Notifiable Disease Incident report form; this report is updated as further information becomes available, until swine fever is either confirmed or negated.

4.2 Actions at premises where disease is suspected

4.2.1 Where AHVLA decide that a VI must visit the premises, AHVLA will orally inform the person reporting the suspect pig/ carcase and/ or the person at the premises responsible for the pigs that:

- further investigation is necessary
- no pigs, carcases or anything which might be infected or contaminated with swine fever virus should be moved off the premises. This is to minimise the risk of further disease spread

4.2.2 On arrival at the premises, the VI will serve the occupier with a written restriction notice (EXD1) designating the premises as a “suspect premises” and formalising the restrictions served orally. Premises where disease is suspected are termed “Suspect Premises”.

4.2.3 The VI will undertake a thorough investigation to determine whether suspicion of swine fever can be negated on clinical grounds. If swine fever is negated the VI will immediately remove the premises restrictions.

4.2.4 If the VI cannot rule out the suspicion of swine fever they will take samples and submit these for laboratory analysis.

4.2.5 The restrictions will remain in force until the presence of swine fever can be confirmed or negated. In some cases the restrictions may be modified or an activity licensed. This might be to allow a specific activity such as the movement on or off the premises of people, vehicles, equipment, other animals (except pigs) or things that might spread disease where the veterinary inspector considers the risk of spreading disease can be mitigated.

4.2.6 The welfare of pigs must be ensured during any period of restriction.
4.2.7 Whilst results are awaited, epidemiological investigations will continue to establish how long disease may have been present, the likely source and whether disease originated at these premises.

4.2.8 In anticipation that swine fever might be confirmed, the VI will start to prepare plans to deal with culling of pigs so that action can be taken quickly if disease is confirmed. This will include liaising with AHVLA on logistics.

4.2.9 The investigation may also identify animals, vehicles and other things that may have already taken disease out of the premises (or brought it into the premises) so that these can be traced (see section 4.3 below on contact premises).

4.2.10 Government will receive and analyse the test results and the government’s CVO will decide that either:

- swine fever is negated: all restrictions will be removed immediately; or
- swine fever is confirmed: the infected premises will remain under restrictions whilst the actions in section 5 are completed

4.2.11 Whilst under investigation, suspect premises must keep a record of further instances of disease, deaths or changes in the livestock and make this information available to officials in order to assess the requirement and regularity of further visits and re-testing.

4.3 Contact premises

4.3.1 Contact premises are places which have a link to a suspect or infected premises which a VI considers may have resulted in the spread of swine fever into or out of the contact premises.

4.3.2 The epidemiological situation and proximity of the premises to an infected premises may lead a VI to conclude that disease may have spread to the premises. The principle of lateral spread of swine fever is supported by evidence from previous outbreaks of CSF in England\textsuperscript{13} and worldwide\textsuperscript{14} which show that outbreaks may be prolonged as a result of spread of disease from an infected premises to pig farms in close proximity, typically 1km to 3km. Similar principles apply for ASF.

4.3.3 The extent of the investigation on the contact premises will be assessed using a risk-based approach. The following actions may be taken:

- the contact premises will be placed under restrictions (similar to a suspect premises) and monitored for a specified period of time
- traced pigs will be clinically examined (and others inspected or examined)
- samples from traced pigs will be submitted for swine fever testing

• the clinical and movement records of the traced animals will be reviewed
• subsequent re-testing should take place if epidemiological evidence suggests that this is appropriate
• movement restrictions will be put in place although movement of things on or off the premises may be licenced by a VI subject to an assessment of the risk of disease spread
• semen, ova and embryos that have been moved during the period when disease may have been present will be traced (and may be destroyed as appropriate)

4.3.4 If considered to be a high risk of disease spread, the pigs at the premises may be culled (as described in section 4.4).

4.4 Killing of pigs at suspect and dangerous contact premises

4.4.1 Ordinarily the CVO would wait for full laboratory results and confirmation of disease before killing pigs for disease control purposes. In some circumstances the CVO may however conclude that to delay killing pigs at a suspect or contact premises presents a serious risk of the spread of swine fever. Scenarios where it is likely the CVO will decide pigs should be killed ahead of formally confirming disease include:
• when disease is not already present in the country or region of the country but there is a strong indication that swine fever is present (such as interim laboratory results combined with a serious or deteriorating clinical picture at a suspect premises) and to delay culling risks the spread of disease (such as in a pig dense area)
• at a suspect premises within an existing control zone where there is a serious or deteriorating clinical picture
• at a contact premises where there are clinical signs of swine fever
• at a contact premises where epidemiological evidence is highly indicative that disease will be present and to delay culling risks the spread of disease

4.4.2 This early cull has the advantage of minimising the level of virus build up and thus reduces likelihood of further accidental spread whilst results are awaited.

4.4.3 Whenever pigs are killed ahead of formal confirmation of disease, sufficient samples will be taken to establish the extent of disease (if any) that was present.

4.4.4 If following laboratory analysis of samples disease is confirmed, the premises will be re-designated as an infected premises (IP).

4.4.5 If, after killing pigs and testing samples from them, test results are negative and disease is not confirmed:
• at a contact premises, preliminary and secondary cleansing and disinfection will always be required as it is possible low levels of virus were present due to
the contact with an IP but not detectable. Restocking controls (in line with section 6.9) will also apply, before restrictions can be lifted

- at a suspect premises with no epidemiological link to an IP, restrictions will usually be lifted immediately with no requirement for full cleansing and disinfection as disease is not present

4.5 Diagnostic investigation

4.5.1 A series of virological and serological tests are undertaken at the National Reference Laboratories for swine fever. Samples are sent concurrently to the AHVLA to test for the CSF virus and to the Pirbright Institute to test for the ASF virus. Interim test results are usually available within 24 hours but some tests take several days to complete. Additional tests can be undertaken when a virus is isolated and these tests may help identify the origin of the virus.

4.5.2 On occasions an investigation may start as a result of an unexpected result in pre-export testing or pre-entry testing of boars at Artificial Insemination centres. AHVLA will investigate these in exactly the same way as they would for a clinical suspect case.

4.5.3 Laboratories finding evidence of the use of vaccine against CSF following analysis of samples must immediately notify their local AHVLA office.

4.6 Epidemiological assessment

4.6.1 A VI will undertake an epidemiological assessment to try to begin to determine the:

- possible origin of the infection
- period during which swine fever may have been present at the premises
- movement of potentially infected animals, carcases or items from the premises
- other premises that may be infected
- possibility that pigs living in the wild may have been involved in the spread of the virus

4.6.2 The VI will continue this enquiry until these facts have been established so far as is possible or the possibility of disease has been discounted.

4.7 Optional controls in the area around a suspect premises

4.7.1 Where swine fever is suspected at a premises and it is placed under restrictions, government will consider whether restrictions on other pig premises in the area are needed pending the outcome of tests. Such a temporary control zone (TCZ) is a precautionary measure designed to minimise the risk of the spread of undetected disease.

4.7.2 In a TCZ the movement of pigs off premises in the zone is restricted. The main purpose of this measure is to prevent the movement of pigs out of the area (and thus the potential to spread swine fever) prior to any future protection zone or surveillance zone (see Section 7) being declared if disease
is confirmed. Government is unlikely to impose further restrictions within the zone but, if these are considered necessary by the CVO, there is flexibility under current domestic legislation for government to apply further restrictions within the TCZ.

4.7.3 The default position is that a TCZ will not be declared when disease is suspected.

4.7.4 However, a TCZ may be considered where there are no confirmed cases of swine fever in GB and if:
   - a decision is taken to kill pigs at the suspect premises ahead of confirming disease
   - evidence suggests that pigs are deliberately being moved out of the area to avoid any future PZ/SZ (Protection and Surveillance Zones)

4.7.5 In addition to the two scenarios above, a TCZ may also be considered when swine fever has already been confirmed in GB and if:
   - there are clinical signs leading to strong suspicion of disease on a contact premises and a decision is taken to kill the pigs
   - the suspect premises is in a pig dense area where there is a high risk of lateral spread if disease is subsequently found to be present. This may include when the suspect premises is close to the edge of a SZ
   - if the suspect premises is not within a PZ/SZ and the veterinary inspector’s assessment of the situation at the suspect premises warrants wider controls

4.7.6 The size of the zone is likely to be the size of an SZ (as a minimum 10 km), although account will be taken of the specific circumstances.

4.7.7 Government will lift the TCZ when disease is negated at the suspect premises or the TCZ will be replaced by a PZ/SZ if disease is confirmed (see section 7).

4.8 Suspicion of swine fever in pigs living in the wild

4.8.1 See section 10.4 for information on when swine fever would be suspected in feral pigs and information on what control measures would be taken.

4.9 Outcome of investigation

4.9.1 There are two possible outcomes:

   i. The CVO confirms CSF or ASF on the basis of laboratory tests and this would be expected within 24 to 48 hours of laboratory samples being received (see next section); or

   ii. Swine fever is negated. If the decision is based solely on a clinical assessment this will be very quick. If the decision is dependent on the results of laboratory tests this can take up to a week for all tests to be completed to verify that swine fever virus was not present.
4.9.2 If suspicion of disease is strong and AHVLA cannot rule out its presence on clinical grounds, government may hold an Amber teleconference. Its purpose is to appraise the relevant government bodies and functions of the situation and risk assessment, and to plan further action and communication accordingly. Please refer to GB governments’ exotic disease contingency plans (see 1.2.1) which detail the mobilisation of teams, the disease control policy groups that will be set up and the communications taking place at this time.

4.9.3 If swine fever is negated, AHVLA will notify the premises’ occupier and the restrictions will be lifted, although other measures may continue at the premises to deal with any other disease found or suspected. Subsequent sections describe actions if swine fever is confirmed.

4.10 Communication

4.10.1 Since the time from initial report to confirming disease is usually quite short (normally within 48 hours) the policy is not to publicise the investigation. Many investigations prove negative and unnecessary publicity can prove disruptive to the premises and could potentially affect trade.

4.10.2 Therefore, it is not usual practice to make public statements about premises that are under investigation for suspect disease. However, general communications to stakeholders may be necessary in certain circumstances. For instance, to raise awareness about the international disease situation, the general disease status and the need for increased vigilance and biosecurity. These communications will be made using existing and appropriate government and industry channels. General advice on biosecurity including information on typical signs of disease is already in the public domain.

4.10.3 Minimal communication with other local premises is undertaken as necessary during suspicion stages to manage the disease risk. As the likely epidemiology of the disease emerges, other premises in the vicinity or identified as potential contact premises may be contacted or the surrounding area could be placed under restrictions (see Temporary Control Zones, section 4.7) if considered necessary to prevent disease spread. Notices and signs may be required at the suspect premises or in a wider area if a TCZ is declared.
5  Confirmation of ASF or CSF in GB

5.1  Confirming a case of swine fever

5.1.1  The CVO for the part of UK which is investigating the suspect swine fever is responsible for taking the decision to confirm disease in their territory. A decision is taken in consultation with the CVOs for the rest of the UK, normally at or following an Amber teleconference. Confirmation of swine fever will be consistent with the requirements of the relevant EU diagnostic manual15.

5.1.2  On confirming the first case of swine fever government takes action to prepare a legal base to control the outbreak, to mobilise resources and to comply with international obligations. The main actions on confirmation of the first case of swine fever are summarised in this section.

5.1.3  Government will invoke the relevant contingency plans and set up the National Disease Control Centre (NDCC) and Local Disease Control Centre(s) (LDCC) in line with these plans.

5.2  International notification obligations

5.2.1  Within 24hrs of confirming swine fever the CVO for the UK will notify the OIE that the swine fever is present in the UK. The CVO UK will also notify the European Commission of the presence of the disease.

5.2.2  The OIE, Commission and EU member states must be kept informed of further outbreaks and be updated with progress on the outbreak by the submission of regular reports.

5.3  Trade and safeguard measures

5.3.1  Government will withdraw export health certificates for pig and pig by-products and will notify importing countries. It is likely that the UK will take voluntary action ahead of the formal confirmation of swine fever to minimise the risk of spreading undetected swine fever to other countries.

5.3.2  On confirming a swine fever outbreak the UK may seek, or be subject to, an EU safeguard measure. This will ratify the action taken by the UK to prevent the export to the EU of live pigs, or other pig products. The safeguard decision may impose additional controls. Export restrictions will apply to a much wider area than that where disease is currently identified to reflect the uncertainty of where else in the country swine fever may already be present. Thus export restrictions will apply to areas of UK which are outside of the control zones (see 7.1) and may initially extend to the whole of GB or UK. The specific measures and areas affected will depend on the precise disease situation and these will be modified as the disease outbreak is brought under control and there is greater certainty about the affected regions.

5.4 Disease control measures

5.4.1 Please see section 6 for details of the control measures taken at infected premises. Section 7 describes the control measures placed over wider areas, in particular the protection and surveillance zones which will be declared around the infected premises in line with EC obligations to limit the risk of local spread. The size of these zones and the control measures imposed in the zones are described in section 7.1.

5.4.2 If swine fever is confirmed in pigs living in the wild, a Feral Pig Control Zone (FPCZ) will be declared. Further information on this and the control measures taken is found in sections 10.5 and 10.7.

5.5 Controls outside protection and surveillance zones

5.5.1 Legislation does not require any specific controls outside of the declared control zones. Multiple zones may be declared or extended as necessary. The measures and procedures to lift these zones are prescribed in EU law. Where there is great uncertainty about the extent of disease, or there are signs of rapid spread over a wider area a decision may be taken to apply controls to areas outside the standard control zones. These controls are more flexible that those prescribed in EU law and so are favoured where there is considerable disease uncertainty and it is expected the measures will be more short term that the prescribed EU zones. These wider movement controls are described in section 7.1.

5.5.2 It is likely that the confirmation of swine fever in GB will lead to increased awareness and as a consequence will lead to an increase in the number of disease notifications. There are no plans for increased random or targeted surveillance beyond that required in protection and surveillance zones to provide evidence of disease freedom and to follow-up tracings from infected premises.

5.6 Cross-border zones

5.6.1 Where disease is confirmed and control zones are established in England, Scotland or Wales and the legal minimum zone size would overlap the other territory, a joint declaration will be prepared.

5.7 Communications and raising stakeholder awareness

5.7.1 During an outbreak, government must make information available for all pig keepers, veterinary practitioners and other stakeholders, particularly within the protection and surveillance zones. The information provided will vary during the course of the outbreak, but will include:

- clinical signs of swine fever
- action to take if swine fever is suspected
- the current disease situation
- current control measures
• legislative and licensing procedures

5.7.2 Livestock owners must be made aware of their responsibilities and the requirements to supply information from premises within zones, for example, recording existing animals, illness, deaths and births.

5.7.3 Owners must be made aware of the results of tests for swine fever performed on their pigs and any restrictions imposed as a consequence.

5.7.4 Livestock owners outside zones also have responsibilities. General and targeted publicity will keep them appraised of the disease situation and help them understand how restrictions may impact their business and the type of biosecurity precautions, vigilance and other practices they might adopt to minimise the risk of exposure to or further spread of swine fever.

5.7.5 An outbreak of swine fever should not have a direct impact on the general public but general publicity will keep them informed about the disease, the outbreak and the control measures being taken. The main message is that swine fever does not have any public health implications. This information will be disseminated in partnership with the relevant government bodies\(^\text{16}\). Advice about food safety should be delivered by the FSA.

\(^{16}\text{The Department of Health and Public Health England in England, Public Health Wales in Wales and Scottish Government’s Directorate for Chief Medical Officer and Public Health}\)
6 Controls at infected premises

6.1 Definition of an infected premises

6.1.1 The term “premises” is used throughout legislation and this strategy. An “infected premises” (IP) is any place where disease has been confirmed and an IP Restriction Notice served.

6.1.2 The IP Restriction Notice will make it clear what constitutes the IP and will take account of factors such as highways which may divide the holding. Even if the premises are in the same ownership or part of the same holding, separate Notices will be served on each premises.

6.1.3 If disease is confirmed on common land, the common will be treated as an IP and the same IP restrictions will apply. Restrictions may apply to inbye land.

6.2 Movement and access controls at IP

6.2.1 Where swine fever is confirmed pigs, carcases or anything suspected of being contaminated with swine fever must not be moved.

6.2.2 Once assessed by an AHVLA veterinary inspector (VI), the movement of people, vehicles, equipment or other animals (excluding pigs) on and off the premises may be licensed by the VI subject to an assessment of the risk of spread of swine fever.

6.2.3 An important measure is to restrict the access of people to the IP to minimise the risk of swine fever being carried to another premises. Footpaths can present a significant risk by allowing general public access to the IP. The VI will assess the threat any public footpath poses to the IP and as necessary AHVLA will work with the appropriate local authority to seek closure of footpaths on the IP which present a disease risk. It is anticipated that footpaths will not need to be closed over a wide area although in some limited circumstances, where the risk of spread of swine fever is high, it may be necessary to seek the closure of footpaths close to an IP.

6.2.4 Upon entry and prior to leaving the premises any vehicles permitted on/off under licence will require cleansing and disinfection.

6.3 Killing of pigs at an IP

6.3.1 All pigs on an IP will be culled as soon as practicable, whether or not they currently show signs of disease. Culling is usually undertaken by licensed slaughtermen under the supervision of a VI. Carcasses will be destroyed under official supervision.

6.3.2 Incineration is the preferred disposal method; rendering could also be an option with other disposal routes available, subject to public health, environmental and land use/planning considerations.
6.4 **Destruction of semen, ova and embryos**

6.4.1 Semen, ova and embryos collected from pigs at the IP during the period between the probable introduction of swine fever to the premises and the implementation of official measures will be traced and destroyed under official supervision in such a way as to avoid the risk of spread of swine fever virus.

6.5 **Cleansing and disinfection (C&D)**

6.5.1 The IP vehicles, equipment and anything likely to be contaminated with swine fever virus will be cleansed and disinfected under the supervision of a VI. Disinfection must be carried out using a disinfectant approved for use in GB\(^\text{17}\).

6.5.2 Vehicles on the premises will need to be unloaded and cleansed and disinfected under the supervision of a VI. Vehicles on the premises will remain there until they have completed full C&D and been licensed to move off the premises by AHVLA.

6.5.3 Any equipment, bedding etc. from the IP will either be destroyed or treated under official supervision. Parts of the premises that cannot be cleansed and disinfected will remain under restriction for an extended period, until notified by the VI that they are satisfied there is no longer a risk of swine fever virus being present.

6.5.4 There will be some items that cannot be cleansed or disinfected, for example contaminated feed, farm waste products and slurry. In such cases the items will be destroyed, treated to inactivate any virus or disposed of appropriately. For instance, manure and used bedding should be stacked, sprayed with disinfectant and left for at least 42 days or destroyed by burning or buried. Slurry from an IP should be stored for at least 42 days for CSF, or 60 days for ASF, after the last addition of infective material. A shorter storage period may be permitted if a VI has given instructions to treat the slurry in some way prior to storage. Slurry from an IP should not be used for spreading.

6.5.5 Government will undertake and fund preliminary disinfection: this is the surface application (normally by spraying) of an approved disinfectant (diluted to the manufacturer’s instructions) to those areas of the premises which have had direct contact with animals (note, this would generally not include fields/pastures etc). The application of the disinfectant is to damp down the levels of virus, to prevent local spread. Owners are responsible for undertaking and paying for secondary C&D, irrespective of whether or not they intend to restock the premises. If the owner does not undertake secondary cleansing and disinfection, AHVLA can arrange for this to be undertaken by others at the expense of the owner\(^\text{18}\).

---

\(^{18}\) Diseases of Swine Regulations 2014 (Regulation 14(3))
6.6 Tracing of meat from animals slaughtered in risk period

6.6.1 Swine fever virus can remain active for months or years in pig meat products and can be a significant source of spread and dispersal of swine fever in pigs. Pigs moved from the IP to slaughter in the period after swine fever may have been introduced but before disease restrictions were imposed may have been infected with swine fever. Therefore, the meat from these pigs may be affected by swine fever and will be traced, withdrawn and disposed of. Animal products potentially infected with swine fever will be disposed of as category 2 animal by-products as defined in the Animal By-Products Regulations19.

6.6.2 The Food Business Operator (FBO) and FSA official veterinarian will be notified by AHVLA that the slaughterhouse has received pigs from an IP and the products from these pigs must be withdrawn and disposed of. The FBO is responsible for disposing of the carcase/meat. If the product has already left the establishment the FBO is responsible for notifying the recipient they have similar responsibilities to dispose of the meat or notify other premises if the meat has been moved. Records must be retained for inspection. Meat must be withdrawn by processors, manufacturers, distributors and retailers as far as retail shelves but not from end consumers.

6.6.3 Compensation is not payable for products withdrawn under these animal products legislation20.

6.7 For ASF only - Measures when tick vectors are suspected or confirmed at an IP

6.7.1 ASF can be transmitted by soft tick vectors. Current evidence suggests there are no known competent vectors for ASF in the UK21. However, if ASF is confirmed in GB, expert advice will be sought regarding the possibility of biological vectors (soft ticks) in the area or whether other mechanical transmission of infected blood could be involved in the epidemiology of the disease. If so, experts will assist in determining the appropriate control measures to be taken at IPs.

6.7.2 EC law requires special measures to be applied if the presence of ASF viable vectors22 is suspected or confirmed on an ASF-infected premises.

6.7.3 If the presence of vectors is suspected or possible on an IP, an inspection of the pigs’ living and resting quarters and the surrounding area should be

---

19Animal By-Products (Enforcement)(England) Regulations 2013; the Animal By-Products (Enforcement)(Scotland) Regulations 2013 and Animal By-Products (Enforcement)(Wales) Regulations 2014

20 The Products of Animal Origin (Disease Control) (England) Regulations 2008 (as amended), The Products of Animal Origin (Disease Control) (Scotland) Order 2008 (as amended), The Products of Animal Origin (Disease Control) (Wales) Regulations 2008 (as amended)

22 Council Directive 2002/60/EC defines a vector as a tick of the species Ornithodoros erraticus
undertaken to establish the presence or absence of vectors (by physical inspection and the trapping of specimens if necessary). Experts will be engaged in the identification and confirmation of competent vectors, as necessary.

6.7.4 If the presence of tick vectors is confirmed:

- the vectors will be tested to confirm or otherwise the presence of ASF
- further monitoring, checking and control measures will be established in the holding and the surrounding area
- the IP will be insecticide-treated in addition to cleansing and disinfection

6.7.5 The control of the tick vector can be very difficult due to its long life cycle, ability to survive long periods without feeding, the possibility of hosts other than pigs and the possibility of hiding deeply in the fissures of buildings where it is difficult to spray with insecticides.

6.7.6 The EU may specify further measures for the monitoring and control of vectors by an implementing decision.

6.8 Compensation

6.8.1 Under the Diseases of Swine Regulations 2014, government will pay compensation for pigs culled for disease control purposes. For pigs determined to be affected with swine fever the compensation will be at half the pig’s value immediately before it became affected. For unaffected pigs slaughtered in order to control swine fever the compensation will be the value of the animal immediately prior to slaughter. AHVLA maintains a list of approved valuers. Only approved valuers may value animals slaughtered for the control of swine fever.

6.8.2 Compensation is also payable on anything seized by AHVLA and not returned, other than when this has been done because a person has failed to comply with their obligations.

6.8.3 Compensation is not available for consequential losses. Compensation is not payable for meat disposed of under the Products of Animal Origin (Disease Control) Regulations 2008 (as amended).

6.9 Repopulation of infected premises

6.9.1 For CSF-infected premises, or ASF-infected premises where disease is not linked to vectors, restrictions will remain in place until:

i) More than 6 months has elapsed since the satisfactory completion of secondary C&D and the VI is of the opinion that restrictions can be lifted without risk of spread of disease; or

ii) Following satisfactory completion of secondary C&D, the premises has been tested for the presence of any remaining disease using sentinel pigs. If no disease is detected in these sentinel pigs, restrictions may be lifted. The
process for this is further explained below.

6.9.2 For (ii), AHVLA will license the sentinel pigs on to the premises after a certain period of time (specified under law) has passed since the owner has satisfactorily completed secondary C&D, as follows:

- At least 40 days for ASF-affected premises
- At least 30 days for CSF-affected premises

6.9.3 The number of sentinel pigs to be used will be specified by the VI and will be the minimum sufficient number to detect disease on the premises. In this context the term “premises” relates to all parts of the holding specified in the IP restriction notice and will include all parts of the holding potentially exposed to disease.

6.9.4 These sentinel pigs must have tested negative for antibodies against the disease (at the expense of the owner) or come from premises not subjected to swine fever restrictions.

6.9.5 AHVLA will undertake serological laboratory tests of the sentinel pigs:

- 45 days after the arrival of the last sentinel pig onto an ASF-affected premises, or
- 40 days after the arrival of the last sentinel pig onto a CSF-affected premises

6.9.6 If these final tests prove negative for swine fever antibodies, AHVLA will lift all restrictions on the premises and the occupier may fully restock.

6.9.7 For holdings where the pigs are kept indoors, the occupier can decide to use a much larger number of sentinel pigs. If a larger number of sentinel pigs are used, all the pigs must arrive within 20 days. The sentinel pigs should have tested negative for antibodies against the disease (at the expense of the owner) or come from premises not subjected to restrictions because of swine fever. These sentinel pigs will be subject to serological testing for swine fever as in 6.9.5.

6.9.8 The same restocking controls apply for dangerous contact premises where pigs have been pre-emptively culled (see section 4).

6.10 Repopulation of ASF-infected premises where the occurrence of disease has been linked to soft tick vectors

6.10.1 In the case of ASF-infected premises where the occurrence of disease has been linked to tick vectors (as in section 6.7), restocking will not take place for at least 6 years unless:

- Specific measures have been carried out, under AHVLA supervision, to eliminate the vector from the premises and other places where the pigs would be kept or come into contact with, or
- It has been possible to show that the persistence of vectors no longer represents a significant risk of ASF being transmitted
6.10.2 Thereafter, the premises will be tested for any remaining disease through the use of sentinel pigs as in paragraphs 6.9.2 – 6.9.6 above. If no disease is detected, the occupier may restock as usual. Restrictions on the premises will not be lifted until at least 60 days has passed since this full restocking.

6.11 Communications

6.11.1 Once disease is confirmed, AHVLA will take steps locally to ensure that everyone in and around an IP is made aware of the restrictions and requirements in force there. This may include displaying notices and signs.

6.11.2 Information will be made available to pig keepers explaining what happens if disease is confirmed on their holding.
7 Measures in Disease Control Zones

7.1 Disease control zone definitions – temporary control zone

7.1.1 See section 4.7 for an explanation of the use of temporary control zones declared where necessary on suspicion of swine fever in domestic pigs.

7.2 Disease control zone definitions – protection and surveillance zone

7.2.1 Where disease is confirmed at an IP, there is an increased risk of disease spreading to pig premises in the vicinity. Therefore, government will declare protection and surveillance zones (PZ & SZ) around the IP in line with EU obligations. The aim of these zones is to reduce the likelihood of lateral and onward spread of disease.

7.2.2 The PZ will be a minimum radius of 3km around the IP and the SZ will be a minimum radius of 10km from the IP.

7.2.3 A decision to make zones larger will be taken based on epidemiological advice, the local structure and density of the industry and the wider disease control benefits weighed against consideration of the practical implications and costs of managing larger zones.

7.2.4 Where new IPs are confirmed within an existing PZ/ SZ, the zones will be reshaped and extended as necessary to comply with the minimum size requirements as set out in legislation. Technically this may be achieved by declaring an overlapping zone. They may be sized larger than the minimum size where this improves disease control or improves practical control on the ground.

7.2.5 If an IP is detected in a geographically distinct area, Government will declare a new PZ/SZ.

7.3 Disease control zone definitions – restriction zone

National Movement Ban

An automatic ban on movements of pigs across GB is not proposed for swine fever. The nature of swine fever suggests a short lived ban adds little benefit in terms of disease control. The practical impacts on industry of a longer ban, and the complexities of determining when the ban should be lifted, argue against any automatic national movement ban at the start of a swine fever outbreak.

7.3.1 Government, in discussion with industry bodies may conclude that further control measures are required over a wider area to supplement the PZ and SZ already declared. In reaching a decision on whether a wider area is required, government will consider whether:

- the PZ/ SZ are insufficient to halt spread of disease with a rapid increase in the number of cases detected over a wider area
• there is a high level of uncertainty about the outbreak source, the linkages between cases, and the underlying degree of undetected swine fever
• there are a large number of potentially high risk tracings
• the strain of virus is believed to be a mild strain which may not present strong clinical signs or a strain which has slow onset of clinical signs
• the European Commission intends to impose further safeguard measures on all or part of GB

7.3.2 The European Commission may discuss with GB government the need for additional safeguards to protect wider EU trade. Such measures may specify an area larger than the PZ and SZ in which:
• movements of pigs from within the area to outside the area are prohibited, unless under licence
• export of pigs and/ or pig products are prohibited

7.3.3 If EU safeguard measures are imposed on an area wider than the PZ and SZ but not GB-wide, government will put in place a wider zone to control movements of pigs from this wider area to other parts of GB.

7.3.4 A possible approach is to extend the size of the surveillance zone to apply to a much wider area. However, EU law is prescriptive of when and how this zone can be lifted (or shrunk) including a requirement to complete surveillance of all premises in the extended zone.

7.3.5 The preferred approach is to use legal powers to control pig movements over a wider area available under Article 5 of the Movement of Animals (Restrictions) (England) Order 2002 as amended, the Movement of Animals (Restrictions) (Wales) Order 2003, as amended and the Movement of Animal (Restrictions) (Scotland) Order 2003. For ease of reference in this document such a zone has been termed a “restricted zone”.

7.3.6 In declaring the restricted zone, all pig movements could be prohibited with certain types of movement being allowed under licence (see section 7.8). Alternatively the declaration may only apply to certain types of pig movement or premises. The optimum approach will be determined on a case-by-case basis. The optimum balance between the disease benefits of restrictions and the negative impact on the day-to-day operations of business is complex to assess. Risks may be reduced by restricting the type of movements that may be allowed and the biosecurity and stand-still requirements necessary to limit the risk of further spread of undetected swine fever. Thus disease risks and economic assessments will be used to help determine the type of zone that is likely to give the maximum overall benefit.

7.3.7 The restricted zone would remain in place until a veterinary risk assessment determines that it is no longer required.

7.4 Impact of multiple control zones

7.4.1 It may arise that a premises is situated in multiple zones. In this case, the
following rules apply based on the general principle that the purpose of the zones is to prevent the spread of disease:

- if a premises is within 2 or more zones the stricter rules apply. Where an activity is permitted in one zone but prohibited in the other the prohibition takes precedence and the activity remains prohibited. Where an activity can be licensed in one zone but not the other (or is not currently being licensed) the activity cannot be licensed

- where one zone is lifted but the other remains in force, the rules for the zone that has not been lifted remain in force.

7.5 Disease control zone definitions – Feral pig zones

7.5.1 Please refer to section 10 for an explanation of the zones declared to control suspected and confirmed disease in feral pigs.

7.6 Disease control zone definitions – vaccination zone

7.6.1 Please refer to section 11 for an explanation of the zones declared where vaccination against swine fever is deployed as a disease control measure.

7.7 Movement prohibitions and derogations in control zones

7.7.1 The focus of the remainder of section 7 is on controls in the PZ and SZ. The Diseases of Swine Regulations 2014 impose controls on the movement of livestock, genetic material, animal products, meat and fomites (any object which may transmit disease) in swine fever PZ and SZ. The aim of these movement restrictions is to prevent the spread of infection.

7.7.2 It is important to understand that even where legislation makes provision to allow something under licence which is otherwise prohibited it does not mean that government will authorise this activity. In considering whether to authorise activity government will need to assess the risk the activity might present to control of the outbreak. Government will consider the phase of the outbreak, the local situation, the risk of disease spread arising from the activity and whether such risks can be mitigated.

7.7.3 During the early phase of an outbreak very tight controls are necessary to prevent spread of, as yet undetected, disease. Generally government will not derogate from these controls in this phase. Whilst there are large numbers of notifications of suspect swine fever, or if government is still confirming new IPs, in particular in and around the declared PZ/SZ, the disease situation will remain uncertain. Thus the risk of spreading undetected disease by authorising movements is likely to be high.

7.7.4 Over time the disease situation stabilises and confidence in the situation in that area increases, although there will remain some uncertainty about the disease situation. In this phase government will start to consider requests for movements. It will assess the level of risk presented by each type of movement requested and what conditions can be set to mitigate any remaining risk of disease spread. Decisions will take account of the
epidemiological situation in the area and nationally, the degree of success in following-up tracings from IPs. Government will coordinate decisions on the principles of what restrictions may be eased through licensing. Decisions are constrained by the relevant EC Directive, which is prescriptive in what movements may be allowed and the earliest time at which restrictions may be eased.

7.7.5 Derogations from the movement restrictions will be made available either via a Specific Licence which is issued in respect of a specific movement request (normally issued via the local disease control centre following central agreement to the principle of licensing), or a General Licence allowing all movements of a certain type. Licences will include conditions with which the licensee must comply.

7.7.6 However, further outbreaks of swine fever or other information about the nature of the outbreak may require a return to the more restrictive phase.

7.7.7 For many of these derogations, EU law sets out minimum periods for allowing movements (for example, see paragraph 7.8.3).

7.7.8 The following paragraphs consider the prohibitions that apply to various scenarios and include comment on the derogations that may become available.

7.7.9 Section 12.1 describes what conditions need to be met in order to lift the control zones.

7.8 Movement restrictions and licences – live pigs

7.8.1 Pigs cannot be moved off or onto premises in the PZ or SZ. Pigs may be moved within a premises so long as they do not cross a public or private road (see paragraph 7.8.6 for more information about when a holding is divided by a road).

7.8.2 Derogations are unlikely to be available in the period following declaration of the zone. However, after a few weeks have passed since the last confirmed case in the area, government may start to consider the case to allow limited movement of pigs off premises in the PZ or SZ:

- for immediate slaughter
- to another premises within the same zone, if welfare problems cannot be alleviated by management or husbandry practices at the premises
- for culling and movement of the carcase to a rendering plant for processing
- pigs may be licensed from outside the control zones onto premises within zones. However, any increase in the numbers of the susceptible pigs in a control zone is undesirable and would only be authorised in very exceptional circumstances

7.8.3 In addition to the above factors, derogations will not be available until at least the following time period has passed:
Table 1: Time periods for movements of live pigs post-incursion

<table>
<thead>
<tr>
<th>Days since preliminary cleansing and disinfection at the infected premises</th>
<th>ASF PZ</th>
<th>CSF PZ</th>
<th>ASF SZ</th>
<th>CSF SZ</th>

<td></td>
</tr>
</tbody>
</table>

7.8.4 The time periods specified above for ASF can be reduced as in the table below if the relevant Minister determines that the sampling and testing programme23 makes it possible to rule out the presence of ASF on the relevant premises. This option may be limited by logistics and available diagnostic resources.

Table 2: Alternative (reduced) time periods for movements of live pigs post ASF incursion

<td></td>
</tr>
</tbody>
</table>

7.8.5 Under very exceptional circumstances, a derogation may be granted earlier if a serious welfare situation has arisen at a premises as a result of a situation that could not be reasonably anticipated (force majeure), such as serious flooding.

7.8.6 Movements of pigs across roads are prohibited, even where the land belongs to the same pig holding. However, government recognise this will present

---

practical difficulties to some pig holdings, particularly outdoor pig farms. Therefore, before the above time periods have elapsed, and taking account of the local disease situation (and as necessary following a risk assessment by official vets) government may consider a derogation to allow the movement of pigs across a public or private road that divides two contiguous pieces of land that belong to the same pig holding. Such movements will require a licence which will be subject to conditions and in all instances pigs must be transported by vehicle and effective biosecurity practices adopted, especially minimising the risk of contaminating a highway with swine fever virus.

7.9 **Movement restrictions and licences – other (non-porcine) animals**

7.9.1 Non-porcine animals are prohibited from leaving premises in the PZ/SZ where pigs are also kept. Movements may be licensed during all phases of the outbreak but will be subjected to conditions to ensure the movement does not spread swine fever.

7.10 **Movement restrictions and licences – genetic material**

7.10.1 Movement of semen, ova or embryos off premises in the PZ or SZ is prohibited, except for disposal at an approved facility.

7.10.2 There are no prohibitions on the movement of genetic material onto a pig premises in the zone.

7.11 **Movement restrictions and licences – carcases, pig products and waste**

7.11.1 Movement of dead stock off pig premises in a PZ/SZ is prohibited but may be licensed, most likely when the disease situation is stable and provided they are clean carcases.

7.11.2 Manure and slurry and other pig waste cannot be moved off a pig premises although it can be licensed for transport for disposal. The transport vehicle must be leak proof and the destination must be approved for handling the waste.

7.11.3 Spreading of pig manure or slurry will be prohibited. It may be licensed, but not until the disease situation is stable and following a veterinary risk assessment\(^\text{24}\).

7.12 **Movement restrictions and licences – vehicles**

7.12.1 Trucks and vehicles that have carried live pigs or other livestock or material which may be contaminated with swine fever virus are prohibited from leaving premises in the PZ/SZ unless they have undergone cleansing and disinfection (C&D). In the PZ, C&D of such vehicles must be inspected and authorised by a VI.

7.12.2 Such vehicles can continue to be used within the premises.

\(^{24}\) Muck spreading remains subject to the relevant environmental rules
7.13 Movement restrictions and licences – feed

7.13.1 Feed should not be moved off a pig holding, unless the feed mill is a separate epidemiological unit. This will be determined by a VI.

7.13.2 Transportation of feed in the PZ/SZ is not prohibited but deliveries should try to avoid entry to pig premises. Best practice C&D should be employed both on entry and exit. Deliveries should be scheduled to high health status premises before other premises.

7.14 Biosecurity at pig premises

7.14.1 The movement control measures on pigs, vehicles and other material likely to spread swine fever significantly reduce the risk of disease entering or leaving premises in the zones. Pig keepers should continue to employ good practice within the premises, including good personal biosecurity such as washing hands and using clean, uncontaminated clothing.

7.14.2 Outdoor pigs are at greater risk of exposure to disease incursion from wildlife (including feral pigs in some areas), public access and other fomites. There is no significant risk of an aerial plume of swine fever virus thus measures to minimise the risk of physical contact with outdoor pigs should help keep disease out. During an outbreak of disease, the owners of outdoor units are encouraged to upgrade their biosecurity and access controls and to seek to separate their pigs from any wildlife threats.

7.15 Surveillance and epidemiological investigations

7.15.1 Within the PZ and SZ, AHVLA will undertake surveillance to assess the extent of lateral spread from the IP. The methodology will be determined taking into account consideration of existing epidemiological evidence available. If surveillance identifies further suspect premises they will be handled as described in section 4.

7.15.2 Surveillance will be assisted by use of data from various sources on the location of registered pig keepers. However, this will be supplemented by AHVLA foot patrols to identify any other pig keepers in the area.

7.15.3 Similarly, data on feral pig populations will be considered and as necessary supplemented by visits by feral pig experts.

7.15.4 Virological and serological surveillance may be carried out for epidemiological purposes and to support declaring previously infected areas (IAs) free from disease.

7.15.5 Veterinary visits to all premises with pigs in the area will take place, to provide advice, to check for disease, and after a certain period to ensure the premises has remained disease free prior to lifting of control zones.

7.15.6 Such data will also be of value to disease modellers and experts to provide advice to veterinary and policy teams. The National Emergency Epidemiological Group (NEEG) will use the evidence obtained from all
sources to assess:

- the possible origin of the infection
- the period during which swine fever may have been present on the premises prior to detection
- the risk of disease dispersal through movement of pigs, personnel, vehicles, carcases, meat or any other material which may have transported virus from the premises
- the risk of other premises that might be infected

7.15.7 The role of NEEG will also include:

- the provision of epidemiological advice and assessment on the determinants, level and distribution of the disease to the National Experts Group and other groups and the UK CVO to inform decisions on disease control and prevention measures including vaccination and surveillance
- leading the epidemiological investigations of the outbreak
- delivering epidemiological modelling
- designing surveillance plans and analysis of these surveillance outcomes
- providing epidemiology reports as necessary

7.16 Communications

7.16.1 Government will deliver a communication programme to inform keepers/owners of susceptible animals, veterinarians and other stakeholders of:

- the disease situation
- measures being implemented
- advice on clinical signs of disease

7.17 Impact of controls

7.17.1 The restrictions set out in this section will impact on day-to-day farm business operations. These measures are necessary to reduce the risk of disease spread and therefore reduce the overall size and duration of an outbreak. These controls are set out here to allow government, delivery agents, pig producers and processors and related sectors to prepare contingency plans in advance of any outbreak of swine fever. Such action can help alleviate the overall impact on businesses and will help manage expectations.

7.17.2 Government recognise that, due to the nature and structure of pig production systems in GB, movement restrictions will have different impacts depending on the structure and set-up of different operations. Controls may affect the businesses’ ability to move pigs in and out of farrowing, to move weaned pigs to growing accommodation or to move finished pigs to slaughter.

7.17.3 This strategy is not intended to directly address such impacts. However, government and industry are committed to working through mitigating and
contingency actions that might alleviate some of the pressures during an outbreak. Pig producers and processors are strongly encouraged to put in place appropriate contingency plans. Government will be working with its delivery agents to ensure they are adequately prepared to respond effectively.
8 Special cases – establishments and animal gatherings

8.1 Disease at establishments, animal gatherings and during transport

8.1.1 There are some possible scenarios in which swine fever is suspected in pigs at a place where the pigs are not usually resident. Examples include establishments (such as abattoirs) or animal gatherings (such as markets or shows). In these special cases, it is likely (but not certain) that the pigs suspected of being affected by swine fever will have arrived at the location already infected. Thus, special procedures apply where swine fever is suspected or confirmed in these cases, as explained further below. Specific rules also apply to establishments and animal gatherings in control zones.

8.2 Suspicion of swine fever in pigs at an establishment

8.2.1 The term establishments is intended to include abattoirs (also known as slaughterhouses where animals are slaughtered with the intention of the animal product entering the human food chain), knackeries’ yards (where animals are killed but not for the human food chain), and game handling establishments (where carcases of pigs killed in the wild may be taken for hanging and meat inspection in order to enter the food chain).

8.2.2 When AHVLA is notified of suspicion of disease in pigs at an establishment, the establishment will be placed under restrictions and further movements of animals onto the premises prohibited whilst investigations take place. The killing of pigs will be halted until the AHVLA VI arrives and assesses the situation. The VI will wish to inspect the pigs prior to slaughter to assist with the assessment. No pig products should leave the establishment until the VI authorises such movement.

8.2.3 Investigations will initially focus on establishing whether swine fever should be suspected and whether samples need to be taken. If swine fever can be negated based on the clinical picture then restrictions can be lifted and normal business resumed. All meat that had been detained is released for sale subject to it continuing to comply with food hygiene requirements.

8.2.4 If samples need to be taken to confirm or negate the presence of swine fever then restrictions will remain in force for 24-48 hours; this will prevent further animals being brought into the abattoir for slaughter. The VI will assess which pigs in the lairage may be infected and take the necessary samples.

8.2.5 The VI will also seek to identify the source of the suspect pigs, including their route to the abattoir. Restrictions will be served by AHVLA on the source premises and any premises visited on route to the abattoir. These will be investigated by AHVLA as contact premises.

8.2.6 Once the VI has completed the initial assessment (including consideration of the chillers and any requirement to cleanse) the VI will give instructions to the FBO on how the remaining pigs may be killed and the carcases and pig by-products stored whilst investigations are undertaken. The intention of this is to
minimise the risk of cross-contamination of potentially affected pigs and pig carcases with those that might be free of swine fever.

8.2.7 Meat that has come from the suspect pig/s, or may have come into contact with such meat, will be detained pending the outcome of the investigation. If swine fever is confirmed this meat will be disposed of as by-product. The FBO is advised to maintain the meat in suitable conditions to ensure that the meat remains fit for human consumption if swine fever is negated and the meat is released for sale.

8.3 Confirmation of swine fever at an establishment

8.3.1 Where swine fever is confirmed in a pig or pig carcase at a slaughterhouse, knackers’ yard or game handling establishment, special measures will apply. The establishment is not treated as an IP as it is likely pigs will have arrived already infected with swine fever, although this may have been transmitted to others in the lairage or carcases contaminated with swine fever virus.

8.3.2 Any remaining pigs will be killed without delay and the meat detained and kept separate from other meat. All meat at the premises will temporarily be detained until the VI has assessed the risk of the meat being infected or contaminated with swine fever virus. Where there is no risk of swine fever infection or contamination, meat may be released otherwise it will be detained pending test results.

8.3.3 Where swine fever is confirmed the FBO will be required to dispose of the affected meat as category 2 animal by-product. The VI will direct what actions are needed, including C&D of the establishment.

8.3.4 Unless the establishment turned out to be the disease source it is likely restrictions will be lifted quickly and the establishment will be allowed to recommence operations. However, restrictions cannot be lifted until at least 24 hours after C&D is completed to the satisfaction of the VI.

8.3.5 Control zones are not ordinarily declared around infected establishments.

8.4 Suspicion of swine fever at an animal gathering

8.4.1 Types of animal gatherings include licenced markets, shows, collection centres and approved export collection centres. Special procedures apply where swine fever is suspected. Animals can remain at gatherings for some time, possibly in excess of 48 hours, and unlike establishments are intended to leave the gathering alive.

8.4.2 When suspicion of swine fever at a gathering is notified, the gathering will be restricted and further movements of animal on or off will be prohibited whilst initial investigations take place. Investigations will initially focus on establishing whether swine fever should be suspected and whether samples need to be taken. If disease can be negated based on the clinical picture then restrictions can be lifted and normal business resumed.

8.4.3 If samples need to be taken to confirm or negate the presence of swine fever
then restrictions will remain in force for 24-48 hours. Only in exceptional circumstances will it be possible to move further animals into or out of the gathering.

8.4.4 Since the gathering is unlikely to be the source of swine fever, the AHVLA VI will seek to identify the source of the suspect pigs. Work will also be undertaken to identify any animals or vehicles which have already left which could potentially be carrying infected pigs or have been contaminated with swine fever. Restrictions will be served at source, destination and other contact premises as the AHVLA VI considers necessary.

8.4.5 AHVLA will treat the gathering in much the same way as any other suspect premises; there are no special provisions available in law. Given the temporary nature of a gathering, effort will also focus on how to minimise the impact of animal welfare whilst results are awaited. Animal gatherings are required to maintain contingency plans and these should include plans to take temporary care of animals, including their welfare during this time.

8.4.6 Subject to appropriate measures to minimise the risk of spread of swine fever, AHVLA will be able to license the movement of other animal species off the gathering. Conditions for this movement will include appropriate C&D of vehicles including the wheels and wheel arches prior to departure and AHVLA may also place restrictions on the destination premises especially where other pigs are present.

8.4.7 If disease is negated all restrictions are removed immediately.

8.5 Confirmation of swine fever at an animal gathering

8.5.1 If swine fever is confirmed, disease will be controlled at the gathering premises in much the same way as any other infected premises (see section 6). The premises will be placed under restrictions. If the premises is assessed to be suitable, culling of all pigs will take place at the gathering. Otherwise arrangements will be made to move the pigs to a suitable place for killing.

8.5.2 Non-swine species may be licensed off the premises by a VI, subject to appropriate biosecurity protocols, including C&D of vehicles on unloading at the destination premises. If pigs are present or kept at the destination premises a VI may decide that the destination premises should be placed under restrictions for a period to ensure disease has not been introduced.

8.6 Suspicion and confirmation of swine fever during transportation

8.6.1 If swine fever is suspected in transit (such as a roadside inspection of a livestock vehicle) a VI will assess the pigs and if swine fever cannot be negated on clinical grounds and samples need to be taken a formal notice will be served restricting the vehicle and pigs. Whilst this suspicion of swine fever in transit is unlikely, this is treated as a special case since the vehicle is unlikely to be the source of swine fever. The vehicle’s route(s) will therefore be traced and AHVLA will place the source and any other contact premises under restriction as necessary.
8.6.2 The vehicle and pigs will be moved to an appropriate location to be determined by the VI where they will (if appropriate) be detained and the destination premises placed under restrictions until test results are received. If disease is negated all restrictions are immediately lifted.

8.6.3 If disease is confirmed, the vehicle will be cleansed and disinfected as directed by a VI. Although the receiving premises may not be the origin of infection it will have been contaminated and there may have been lateral spread of swine fever from it whilst the outcome of tests was awaited, thus it will be declared as an infected premises (see section 6).

8.7 Communications when suspicion of swine fever at an establishment or gathering

8.7.1 It is not usual practice to make public statements about premises that are under investigation for suspect disease. However, where swine fever is suspected at an establishment or animal gathering it is necessary to inform farmers who may intend to bring animals to or collect them from such places. Such communication is undertaken primarily by the operator. However, this will lead to media and other enquiries and some limited communication will be undertaken by government when swine fever is suspected at these types of premises. These communications will be limited to the basic facts and it is not normal practice to publicise further details until the outcome of the investigation is known.

8.8 Control of establishments in protection and surveillance zones

8.8.1 To operate a slaughterhouse in certain zones or for them to receive pigs from certain zones they must be “designated”\(^\text{25}\). This requires an application to be made to the FSA who will verify their application and ensure they can meet the requirements for sourcing pigs and separation as necessary, have sufficient C&D facilities for hauliers and have clear processes for handling any restricted meat produced.

8.8.2 Pigs originating outside the PZ/SZ and slaughtered at a slaughterhouse outside the PZ/SZ will not be subject to any additional controls, save any imposed in wider movement restriction or other control zones. There is no requirement for the slaughterhouse to be designated or for the meat to be controlled or (heat) treated. The practice of allowing C&D of vehicles away from the slaughterhouse may be suspended if the disease situation requires.

8.8.3 The movement of pigs from outside the PZ/SZ to a slaughterhouse located within the zones may be licensed from early in the outbreak as the movement is from a low disease risk area to a slaughterhouse for immediate slaughter. Slaughterhouses operating within a control zone must be designated, and if located within the PZ government will need to seek approval from the EC

---

\(^{25}\) The Products of Animal Origin (Disease Control) (England) Regulations 2008 (as amended), The Products of Animal Origin (Disease Control) (Scotland) Order 2008 (as amended), The Products of Animal Origin (Disease Control) (Wales) Regulations 2008 (as amended)
Standing Veterinary Committee.\(^{26}\) There are no controls on the meat produced from pigs originating from outside the zones. The practice of allowing C&D of vehicles away from the slaughterhouse will be suspended in these circumstances and they must fully C&D prior to leaving the slaughterhouse.

8.8.4 It will be a condition of the movement licence for pigs coming from outside the zones for slaughter at a slaughterhouse in the zone that the slaughterhouse must be designated to receive such animals. There is no requirement to control meat plants or other places receiving carcases or meat from animals originating outside the PZ/SZ but slaughtered within the PZ/SZ.

8.8.5 Once pigs originating from within the PZ/SZ can be licenced to slaughter they must go to a slaughterhouse designated to slaughter animals from the PZ/SZ. Ideally the slaughterhouse will be located within the PZ/SZ, but regardless of location it must be designated.

8.8.6 Meat produced from pigs originating from the PZ/SZ (regardless of where they were slaughtered) is termed “Restricted Meat”. Such meat receives a special mark (a crossed through oval health mark) and cannot be sold fresh. It must be treated at a designated treatment centre and prior to treatment only handled at designated premises.

8.8.7 Once the PZ/SZ are lifted, live pigs from those areas become free to be slaughtered in the same way as any other pig from outside a PZ/SZ and meat from pigs slaughtered after zones are lifted can be traded freely. However, meat from animals slaughtered from the PZ/SZ prior to the zones lifting remains restricted and must continue to be handled at designated premises and must be (heat) treated.

8.8.8 Note, in some circumstances the European Commission may take additional safeguard measures that apply to pigs, pork and pork products produced within the GB/UK or a region of the UK. Should this happen, additional measures, such as special marking and trade restrictions may be imposed. Where a special stamp is proposed to indicate meat is restricted to the domestic market, it is likely a round stamp will be adopted.

8.9 Control of animal gatherings in protection and surveillance zones

8.9.1 No animal gatherings in the PZ or SZ will be allowed to have pigs present. Gatherings of other species may be allowed subject to appropriate biosecurity and being separated from any pig premises such that there is no risk of disease spread.

8.9.2 If at the time a PZ/SZ is declared, a market, show or other gathering has pigs present, movements on and off that premises will be prohibited. During this time the gathering is treated like any other premises, and animal gatherings have contingency plans in place in order to care for animals during this time.

\(^{26}\) The EC Standing Committee on Plants, Animals, Food and Feed (SCoPAFF).
8.9.3 Non-swine animals at the gathering will be allowed to leave the gathering as soon as is practically possible, subject to appropriate C&D measures. If the animals return to a farm where pigs are present, a VI may decide that the destination premises should be placed under restrictions for a period to ensure disease has not been introduced.

8.9.4 Approximately 48 hours is needed to allow a preliminary assessment of the disease situation. Subject to veterinary risk considerations and licensing by a VI, pigs may then be licensed to leave the gathering and move to the farm of origin, farm of a new owner, or to slaughter as requested by the pig keeper/owner. A VI may decide that the destination premises should be placed under restrictions for a period to ensure disease has not been introduced.
9 Breeds at risk and other specialist pigs

9.1 Defining breeds at risk and other specialist pigs

9.1.1 Swine fever disease controls could have a direct impact on the survival of various pig breeds at risk (i.e. numerically rare pigs). Diverse genetic resources are important for maintaining an efficient and sustainable farming industry, and they allow the development of breeds to cope with new demands e.g. climate change. In addition, the UK government has international obligations to conserve agricultural diversity. Pigs bred for scientific, research, display or educational purposes (such as zoos or wildlife parks) are similarly important resources. For ease of reference, these pigs will be referred to as “breeds at risk or other specialist pigs”.

9.1.2 The Farm Animal Genetic Resources Committee (FAnGR Committee) has published the list of approved UK pig breeds at risk and the associated criteria at https://www.gov.uk/government/publications/uk-breeds-at-risk-from-exotic-animal-disease-outbreaks. This is not a closed list, and if evidence can be provided to support the criteria, the committee will consider further submissions to include additional breeds on the list. Equally, a breed can be removed from the list if it no longer fulfils all criteria.

9.2 Responsibilities when swine fever is not present

9.2.1 It is essential that the keepers of breeds at risk or other specialist pigs adopt effective biosecurity and hygiene at all times in order to minimise the risk of incursion of any animal disease (be it endemic or exotic).

9.3 General measures during a swine fever outbreak

9.3.1 EC law allows member states to consider derogating from culling of breeds at risk and the other categories of specialist pigs defined in point 9.1.1 provided that disease control is not jeopardised. As detailed below, government will consider such exemptions in exceptional circumstances on a case-by-case basis and will place obligations on the pig keeper to put in place specified mitigating measures to minimise any disease risks the exemption creates.

9.3.2 It is the responsibility of the pig keeper to notify the AHVLA VI if breeds at risk (or other specialist animals) are present on a suspect or contact premises.

Keepers in GB can also register with AHVLA that they have breeds at risk pigs on their premises in advance of a disease outbreak. Information of how to do this is at http://www.defra.gov.uk/animal-diseases/controls/culling-exemptions/.

This registration does not guarantee that breeds at risk animals on the premises will be spared but it will help give advance information to AHVLA officials that can be used during an outbreak.
9.3.3 It is important to note that any exemption from culling applies only to pigs eligible for special measures on the premises, which for breeds at risk pigs includes registration with the relevant breed society; other pigs on the same premises would not be exempt from culling.

9.4 Premises in control zones

9.4.1 The movement controls described in section 7 will apply to breeds at risk and other specialist pigs (no special measures will apply). It is therefore important for owners of such pigs to develop appropriate contingency plans, in particular to avoid welfare issues arising.

9.5 Dangerous contact premises

9.5.1 Section 4 describes how some premises may be identified as dangerous contacts due to epidemiological links (i.e. tracings of pig movements or proximity to an infected premises). Where the risk of exposure of pigs to swine fever is considered to be high, pigs may be pre-emptively culled in order to limit the risk of further disease spread.

9.5.2 Breeds at risk and other specialist pigs may be exempted from the cull of animals on such dangerous contact premises where it does not undermine disease control aims. However, suitable isolation facilities must be available on farm to house pigs spared from any cull, and strict biosecurity protocols must be followed to ensure that disease control is not jeopardised. The measures put in place need to be appropriate to prevent any spread of swine fever virus (either entering or leaving the isolation facilities).

9.5.3 The decision to spare any pig from culling will be taken by the relevant Minister, informed by veterinary risk assessment and other expert advice.

9.5.4 When a decision is taken to spare animals on a premises, the VI will serve a notice on the occupier of the premises on which they are kept detailing the biosecurity arrangements that the occupier must follow to minimise the risk of spread of disease. Any non-compliance with conditions could lead to an immediate withdrawal of the exemption and the culling of pigs.

9.5.5 The spared pigs will be regularly inspected and tested for swine fever before, during and after completion of the isolation period to determine the disease status of the pigs throughout.

9.5.6 Measures will be lifted following veterinary risk assessment on a case-by-case basis. If at any stage swine fever is confirmed at the premises, it will become an IP. The procedures in section 6 will apply unless exemptions in section 9.7 are agreed.

9.6 Suspicion of swine fever

9.6.1 If swine fever is already confirmed in the country, and the clinical signs are such that disease is highly likely at the suspect premises, the CVO may decide that pigs on the premises should be culled on suspicion of swine fever instead of waiting for disease to be confirmed. Where the CVO is made aware
of the presence of breeds at risk or other specialist animals at such a premises it is likely these pigs will be spared from being culled on suspicion of swine fever but the premises would remain under strict biosecurity restrictions whilst laboratory results are awaited.

9.7 Confirmation of swine fever

9.7.1 EU law requires pigs at an IP to be culled quickly. However, in exceptional circumstances, breeds at risk or other specialist pigs may be exempted from such culling, provided disease control is not jeopardised. Isolation facilities will need to be available on farm to house pigs spared from any cull, and strict biosecurity protocols must be followed to ensure that disease control is not jeopardised.

9.7.2 The decision to spare a pig from culling on an IP would be taken by the relevant Minister. The decision will take into account a variety of factors including a veterinary risk assessment, expert advice (e.g. on farm animal genetic resources) and wider risks and impacts such as trade impacts and the need to extend the time that disease control measures remain in place and delays to lifting control zones. Government will immediately notify the Commission of such a decision who will review the situation with the EC Standing Veterinary Committee. The Commission may impose additional safeguards on UK, GB or an area of GB. A decision to spare pigs at an IP will therefore only be taken in exceptional circumstances. To date no circumstances have been identified that would justify exempting infected pigs from culling.

9.7.3 Pigs spared from the cull will be required to be regularly inspected and tested before, during and after completion of the period of isolation to determine the disease status of the pigs throughout.

---

27 The EC Standing Committee on Plants, Animals, Food and Feed (SCoPAFF).
10 Pigs living in the wild

10.1 General points on swine fever and feral pigs

10.1.1 Wild boar and other feral pigs are susceptible to swine fever and therefore can potentially have a role in the spread of swine fever. Once swine fever has affected the feral pig population there is a risk of dispersal of swine fever over wider areas and the introduction from feral pigs into domestic pig premises. Under EU law, the UK is obliged to eradicate any incursion of swine fever into feral pigs and until this is complete there are likely to be trade implications. Once swine fever has entered feral pigs, demonstrating disease freedom in these wild populations is inherently more difficult than at a closed pig premises.

10.1.2 The feral pig situation in GB varies significantly from the rest of Europe in terms of population size, land management practices and natural environments. In GB feral pig populations are relatively small, but dynamic, with the largest of 4 distinct populations being over 200 pigs. Populations can be a mix of domestic pig breeds, escaped farmed wild boar and hybrids. The rest of Europe has much larger populations of feral wild boar with free movement between countries along very large corridors of forest. Much of Europe has a significantly larger hunting industry compared to that in GB.

10.1.3 A qualitative veterinary risk assessment on the likelihood and impacts of transmission of swine fever between feral pigs and domestic pigs concluded that, whilst there are various potential routes for swine fever to be introduced into feral pigs, including the consumption of infected pork products that have been illegally imported, the most likely route of introduction is from infected domestic pigs. Therefore, the risk of introduction into feral pigs can be mitigated by maintaining and enforcing current disease control procedures and maximising biosecurity on domestic pig holdings.

10.1.4 The keeping of wild boar is covered by the Dangerous Wild Animals Act 1976 and therefore a licence is required from the local authority that will set out the conditions necessary to ensure the animals are kept securely. The release of wild boar would be a breach of these licence conditions. Furthermore, wild boar are included within Schedule 9 of the Wildlife and Countryside Act 1981, as amended, which makes it illegal to release or to allow wild boar to escape into the wild.

10.1.5 When swine fever is absent from the UK, wild boar management policy does not require the eradication of feral pigs. Local communities and individual landowners have primary responsibility for feral wild boar management, including population control. Where practical, Government will facilitate this

regional management through the provision of advice and guidance.

10.1.6 In order to assess the likelihood of feral pigs being involved in an outbreak, information on the location of feral pig populations is collated as normal business practice and made available to experts at the start of any outbreak.

10.2 Presence of feral pigs in protection or surveillance zones

10.2.1 Regardless of whether or not swine fever is suspected in feral pigs, whenever there is an incursion of swine fever into domestic pigs, epidemiologists will quickly require information on the presence or otherwise of feral pigs in and around protection and surveillance zones to assess their potential role in the specific incursion and to model potential spread.

10.2.2 The VI’s inspection of the IP will include an assessment of whether there is any sign of feral pigs being involved in the disease incursion.

10.2.3 Relevant bodies (e.g. Natural England (NE), Science and Advice for Scottish Agriculture (SASA) and Natural Resources Wales) will be immediately consulted to advise if feral pig population data indicate that feral pigs are present within the protection and surveillance zones. A field inspection may also be undertaken to provide additional evidence on the presence/absence of feral pigs in domestic pig control zones.

10.2.4 If feral pigs are determined to be present within the protection or surveillance zones, an emergency meeting of a feral pig expert group will be convened immediately to:

- agree necessary actions to improve information on the feral pig population numbers, density and distribution
- to start to consider the likely size of a Feral Pig Investigation Zone in case swine fever were to be suspected in feral pigs

10.2.5 Passive surveillance of feral pigs in the area will be undertaken, including testing of feral pigs found dead or shot. Domestic pigs in the protection and surveillance zones will continue to be monitored by pig keepers.

10.2.6 Ordinarily the size of the domestic pig protection or surveillance zones would not take account of the presence of feral pig populations. However, if further infected premises are identified in the area with no clear link and epidemiologists cannot rule out feral pigs involvement in spread, expert advice will be sought on whether the shape or size of the protection and surveillance zones should be changed to take account of the feral pig population.

10.2.7 Experts advise that the indiscriminate killing or taking of feral pigs without appropriate controls will risk both the dispersal of feral pigs (risking the spread of undetected disease) and carcases not being presented for examination. Therefore the killing or taking of feral pigs will be prohibited in surveillance and protection zones but allowed under licence on premises with pigs to prevent an incursion by feral pigs.
10.3 Detecting swine fever in feral pigs

10.3.1 Under the current surveillance programmes for wildlife, any unusual mortality or disease reported in feral pigs is investigated in consultation with the relevant administration within GB (see below for details). Also the FSA inspects carcases of shot feral pigs presented at game handling establishments and any suspect cases are followed-up through the normal “report cases” system. No further disease surveillance in feral pig populations is intended when swine fever is absent from the UK.

10.4 Suspicion of swine fever in feral pigs

10.4.1 There are two scenarios:

Scenario a) - Swine fever is not known to be present in domestic pigs in the area but unusual mortality or signs of disease are observed in feral pigs.

These signs will be investigated in consultation with the relevant administration within GB. If carcases are available these will be examined and where necessary samples taken. Vigilance for signs of swine fever in domestic pig populations is considered the most appropriate route to identify the first case of swine fever in GB. If swine fever was absent from GB it is unlikely swine fever will be suspected in pigs living in the wild without very strong evidence.

Scenario b) — Swine fever is present in domestic pigs in GB.

Swine fever would be suspected in feral pigs in or around a protection or surveillance zone if:

- unusual mortality or signs of disease are observed in feral pigs
- feral pigs or fresh evidence of feral pigs entering an IP during the period a veterinary inspector suspects disease may have been present or introduced
- there was other strong epidemiological evidence

10.5 A Feral Pig Investigation Zone

10.5.1 Following initial investigations government may conclude that it officially suspects swine fever may be present in feral pigs and further action is needed to confirm or negate this suspicion. The appropriate Minister may then declare a Feral Pig Investigation Zone (FPIZ).

10.5.2 Government will consider the size and shape of a FPIZ on a case-by-case basis, taking account of expert advice. Key factors in determining the size and boundaries of a FPIZ will be the feral pig population size, its distribution, and the surrounding habitat and geographical barriers.

10.5.3 All feral pigs shot or found dead within the FPIZ must be presented for testing.

10.5.4 It is unlikely sufficient carcases will be found naturally to confirm whether disease is present or absent. Therefore, in order to move more rapidly from this uncertain stage, feral pigs will be tracked and killed by experts employed
by Government delivery agents and the carcase tested for swine fever in order to determine whether swine fever is present.

10.5.5 However, the taking or killing of feral pigs would otherwise be prohibited, except under licence on pig farm premises to prevent an incursion onto the premises by feral pigs (which could risk the introduction of disease to domestic pigs). All feral pig carcases must be presented to government for testing.

10.5.6 In certain circumstances, it may be considered proportionate to introduce certain controls on pig premises in a FPIZ to reduce the risk of disease spreading to domestic pigs or to other areas. These can include some or all of the controls available in a Feral Pig Control Zone (see paragraph 10.7). Such a decision will depend on the epidemiological situation and be based on expert advice. Government will work closely with industry to introduce appropriate controls on a voluntary basis in a FPIZ.

10.5.7 The FPIZ will not be lifted until swine fever has either been confirmed or negated in feral pigs. Disease will be negated based on epidemiological and expert advice taking into account the size of the feral population and its local structure, and the number and results of samples taken.

10.6 Confirmation of Swine Fever in feral pigs

10.6.1 The relevant CVO will confirm disease in feral pigs after laboratory confirmation of the presence of swine fever virus and following a teleconference between GB CVOs. On confirming disease in feral pigs a Feral Pig Control Zone (FPCZ) will be declared. The size of the zone will need to be determined based on expert advice and the local circumstances (see point 10.5.2 above).

10.6.2 Government, working with its delivery agents will prepare a swine fever eradication plan, which must be submitted to the European Commission within 90 days of confirmation of the first case of swine fever in feral pigs. This may require further investigation on the ground and contribution from experts.

10.6.3 Disease eradication policy is to, as far as practical avoid dispersing disease beyond its current location. In order to eradicate disease and in-line with policy on domestic pig holdings, the policy is to cull feral pigs to eliminate disease using expert trappers / hunters employed by Government delivery agents. Experts will advise on the most appropriate disease eradication methods for the particular location and feral population. The use of vaccination is discussed in section 11 but it is thought its application on feral pigs will not lead to rapid eradication and given the long-term trade impacts of employing vaccination it is not a control method of choice.

10.6.4 In order to reduce the risk of disease dispersal via feral pigs, the taking or killing of feral pigs would be prohibited except on farm premises to protect stock from a feral pig incursion or killing by expert trappers/ hunters. Each carcase should be examined and tested for notifiable diseases by trained personnel (under veterinary supervision) and also retained whilst testing is
undertaken so infected carcases are not released. Infected carcases will be rendered.

10.6.5 The meat from feral pigs from a FPCZ that are confirmed free of swine fever by testing, would be controlled, specially marked and treated (heat-treated) prior to being allowed to enter the food chain.

10.7 Control Measures in a Feral Pig Control Zone

10.7.1 The following measures will apply to premises in a FPCZ with pigs to prevent disease incursion or spread in domestic pigs:

- prevention of contact between feral and domestic pigs. All the pigs on the premises should be restricted to their living quarters or to some other part of the premises where they can be isolated from feral pigs and feral pigs should be prevented from gaining access to any material that might come into contact with the pigs on the premises

- restriction of pig movements - pigs should not be moved on to or off a premises unless this is licensed by a VI

- appropriate means of disinfection should be provided and used at the entrances and exits of those parts of the premises in which pigs are being kept and of the holding itself

- no carcase or any part of a feral pig should be brought onto a premises in the FPCZ

- no material or equipment which could have been in contact with a feral pig in the infected area should be brought on to a premises

- the occupier of a premises must ensure that a census of pigs on the premises is kept up-to-date and provided when requested by a veterinary inspector (the first census may be based on an estimate for outdoor pigs)

10.7.2 Other controls in a FPCZ will be:

- no pig, semen, ovum or embryo should be moved out of the control zone except under licence. These must not be exported to other EU member states

- any person who comes into contact with a feral pig in the infected area should take steps to ensure that he/she does not spread the swine fever

- any person who finds the carcass of a feral pig should immediately inform officials so that the carcase can be sampled and tested for swine fever

10.7.3 The FPCZ will be lifted after disease eradication is completed but in line with EU law, monitoring will continue in the area for at least 24 months after the last case of swine fever in feral pigs in order to support disease freedom (see section 12.4).
11 Vaccination

11.1 Availability of vaccines

11.1.1 Currently there is no effective vaccine against ASF and EU law prohibits the use of ASF vaccine. Therefore, this section sets out the vaccination policy for CSF only.

11.1.2 The only CSF vaccine considered viable for use in the UK is a live attenuated C-strain vaccine. This is highly effective in domestic pigs, providing rapid immunity from a single vaccine dose. It has also been used effectively in mainland Europe through the use of baits to control CSF in feral pigs. Laboratory testing of pigs cannot differentiate between pigs vaccinated with this vaccine and those pigs which have been affected by a field strain of the virus, thus the strict controls outlined in this section apply to minimise the risk of disease spread.

11.1.3 It is possible other vaccines will become available from time to time. A key factor in deciding whether they are of value will be how quickly they provide immunity against CSF and whether it is effective and reliable.

11.1.4 The general principles of this strategy are unlikely to change fundamentally unless a sufficiently effective marker vaccine became available. This type of vaccine allows tests to be performed to confirm whether a pig has been vaccinated against CSF or whether it has been affected by a field strain of live CSF virus. Such a vaccine, coupled with an appropriate testing strategy, spot checks on the implementation of the vaccination campaign and changes to the trade agreements might allow some of the above restrictions to be eased, in particular around the controls on meat from vaccinated pigs. This would be subject to agreement with the European Commission.

11.2 Use of vaccination to control swine fever

11.2.1 Vaccination of pigs against swine fever provides an additional method of controlling the spread of swine fever. However, decisions to vaccinate are complex. Vaccination is not a cure for swine fever but can prevent pigs from becoming infected. It might therefore be a useful tool in stopping swine fever spread to currently unaffected regions by vaccinating groups of pig farms in or surrounding an affected area to reduce the risk of disease leaving, or in a currently unaffected region to prevent entry. It can also be used within an individually infected or suspect farm to reduce the build-up of virus whilst culling takes place. These measures can therefore reduce the number of premises that eventually become infected with CSF and need to be culled out.

11.2.2 In many circumstances vaccination will not be an effective control method:

- vaccination is expensive both to purchase the vaccine and to deploy requiring the use of qualified people, normally by veterinarians, to vaccinate pigs

- a vaccination campaign distracts vets from the primary task of identifying and controlling swine fever. Depending on the vaccine it can take several doses to
give immunity and the vaccine can need topping-up regularly (although the C-strain is an effective single dose vaccine)

- the vaccine takes a period of time to provide immunity. During this time the pigs remain vulnerable to infection. Vaccine can suppress the signs of infection leading to apparently healthy pigs shedding virus

- international trade restrictions apply once any pigs are vaccinated and these will take longer to ease than disease control without vaccination. Indeed the presence of vaccinated pigs in the national herd could make it difficult or impossible to re-establish trade although this will in part depend on the type of vaccine available

11.2.3 Policy is not to use vaccination as a routine control measure. Vaccination is unlikely to be considered as an appropriate control measure in the initial stages, or during a controlled CSF outbreak.

11.2.4 The use of vaccination may be considered during a prolonged epidemic, where there is a dramatic increase in the number of premises where disease is being confirmed each day, or in areas of very high pig density. Its most likely application is to reduce the risk of infection and spread prior to culling of pigs.

11.2.5 It is unlikely vaccination would be an appropriate control method to control CSF in the small feral pig populations present in GB. However, in the exceptional circumstances that the policy set out in section 10 is unsuccessful in controlling disease in pigs living in the wild (feral pigs), vaccination may be considered. It is likely in such circumstances that vaccine would be applied through baiting and experience on the continent suggests that several periods of baiting are needed to provide immunity in the feral population.

11.2.6 We will consider whether there is a case for vaccinating breeds at risk on a case-by-case basis but only as part of an emergency CSF vaccination plan.

11.2.7 CSF vaccine, if required, will be sourced from the EU bank.

11.3 Legal obligations

11.3.1 The use of vaccination against CSF is ordinarily prohibited\(^\text{30}\). However, vaccination may be used to control disease where epidemiological data suggests CSF is likely to spread if an emergency vaccination plan is submitted to, and agreed by, the European Commission. Thus within GB, a person may only administer CSF vaccine to a pig if authorised to do so by the relevant Minister.

11.3.2 Before initiating a CSF vaccination campaign, government must submit a CSF vaccination plan to the European Commission for approval, setting out how the campaign will operate and the controls that will apply. Whilst there are generic controls it is likely the content of a plan will be determined by the

\(^{30}\text{Regulation 28 in the Diseases of Swine Regulations 2014}\)
specific circumstances of an outbreak.

11.4 Controls if vaccination is used

11.4.1 Vaccination zones would be put in place and some restrictions would apply primarily to control the application of CSF vaccine and the movement of pigs out of the zone and to slaughter. Export restrictions would also apply to vaccinated pigs.

11.4.2 Restrictions will remain in force for at least 6 months after the last pig in the vaccination zone is vaccinated, or earlier if all pigs in the holdings where vaccination has been used have been killed. The detailed controls will be determined according to the circumstances of an outbreak. However, it is expected they will include:

- ban on all pigs leaving the vaccination zone, except where a VI licenses their movement to a designated slaughterhouse
- ban on seropositive pigs from leaving their holding except to slaughter
- ban on collection of semen, ova and embryo from seropositive pigs
- restrictions on the movement of piglets of seropositive sows
- meat from vaccinated pigs must be treated (cooked) prior to sale. Note this is an animal health measure and subject to the usual food hygiene controls is safe to eat
- control on reintroduction of pigs

11.4.3 Note, a seropositive pig is a pig that on serological laboratory testing gives positive test results, indicating that it was at some stage affected by the CSF virus. In a vaccination zone this will normally be as a result of vaccination, but it is possible a pig has also been infected with a live field strain before it developed full immunity therefore a seropositive pig might have been infected. Only certain marker-type vaccines would allow this fact to be established.

11.4.4 Government may decide that it is necessary to vaccinate feral pigs to control and eradicate CSF. In which case, government will submit a plan to the European Commission, including the measures taken to avoid the spread of disease to domestic pigs. We anticipate this will require pig holdings in the affected area to:

- maintain effective barriers to the entry of feral pigs onto the holding
- to report any feral pigs found dead
- a ban on shooting unless licensed by a veterinary inspector to protect domestic pigs
- it is likely the holdings will already be in a “feral pig control zone” and such restrictions will already apply
12 Gaining disease freedom

12.1 Removal of control zones

12.1.1 Zones will remain in place until they are amended or repealed by further declaration on behalf of the relevant Minister.

12.1.2 We will not lift protection zones until:

- all necessary cleansing and disinfection (C&D) has been carried out at all infected premises in the zone to the satisfaction of a veterinary inspector
- pigs on all holdings have undergone clinical and laboratory examinations carried out in accordance with the diagnostic manual in order to detect the possible presence of swine fever virus

12.1.3 For CSF, these examinations should not take place until at least 30 days after the satisfactory completion of preliminary C&D on the infected premises to which the zone relates.

12.1.4 For ASF, examinations in a protection zone should not take place until at least 45 days after the satisfactory completion of preliminary C&D on the infected premises to which the zone relates. This can reduced to 30 days if the relevant Minister determines that the sampling and testing programme makes it possible to rule out the presence of ASF on the relevant premises. This latter option may be limited by logistics and available diagnostic resources.

12.1.5 We will not lift surveillances zones until:

- all necessary C&D has been carried out at all infected premises in the zone to the satisfaction of a veterinary inspector
- pigs on all holdings have undergone clinical and, where the inspector considers it necessary, laboratory examinations carried out in accordance with the diagnostic manual in order to detect the possible presence of swine fever virus

12.1.6 For CSF, examinations in the surveillance zone should not take place until at least 20 days after the satisfactory completion of preliminary C&D on infected premises to which the zone relates.

12.1.7 For ASF, examinations in the surveillance zone should not take place until at least 40 days after the satisfactory completion of preliminary C&D on infected premises to which the zone relates. This can be reduced to 20 days if the relevant Minister determines that the sampling and testing programme makes it possible to rule out the presence of ASF on the relevant premises.

31 This programme will as a minimum be that set out in the EU Diagnostic Manual for ASF http://eur-lex.europa.eu/LexUriServ/LexUriServ.do?uri=OJ:L:2003:143:0035:01:EN:HTML
32 This programme will as a minimum be that set out in the EU Diagnostic Manual for ASF http://eur-lex.europa.eu/LexUriServ/LexUriServ.do?uri=OJ:L:2003:143:0035:01:EN:HTML
This latter option may be limited by logistics and available diagnostic resources.

12.1.8 It is likely zones will remain in place for at least 2 months even for the smallest outbreaks and considerably longer if ongoing sporadic cases continue to be suspected or detected in the area.

12.1.9 Our policy is not to apply compartments (allowing easing of restrictions earlier in non-risk compartments). However, in an extended outbreak and where the disease is localised either geographically, or within a pyramid or sector this may be reviewed.

12.2 Trade within the EU

12.2.1 Trade within the EU is regulated and the restrictions only apply to pigs or pig products which come from the areas under restrictions. These restrictions lapse when the area restrictions are withdrawn subject to compliance with EU law.

12.2.2 Where the EC has imposed a safeguard measure, which is likely, evidence will be provided to the Commission to seek removal of these safeguards once the area restrictions have been lifted.

12.3 Trade with Third countries

12.3.1 There is no requirement or specific procedure for obtaining official recognition of disease freedom from ASF by the OIE. The UK may declare itself free of ASF when it complies with the required measures in Chapter 15.1 of the OIE (World Organisation for Animal Health) Terrestrial Animal Health Code. This requires the collection of relevant surveillance and epidemiological information which may need to be presented to the EU to remove safeguard measures and as necessary to importing countries as proof of the disease situation.

12.3.2 To be recognised as officially free of CSF by the OIE, the UK must submit evidence to the OIE to maintain or regain its CSF free status. This evidence must conform to the surveillance requirements contained in Chapter 15.2 of the OIE Animal Health Terrestrial Code and must be submitted to and accepted by the OIE before disease free status can be obtained. This requires the collection of relevant surveillance and epidemiological information which may also need to be presented to the EU to remove safeguard measures.

12.3.3 Notwithstanding OIE recognition of freedom, trade with third countries may be negotiated ahead of official freedom. Some third countries may require additional assurances before they will trade, regardless of OIE status. Thus bilateral negotiations between governments and industry are important aspects of re-establishing trade with third countries.

12.4 Pigs living in the wild

12.4.1 If swine fever is confirmed in pigs living in the wild, then special measures and monitoring must continue for at least 24 months after the last case of swine
fever in feral pigs in order to support disease freedom. Until this monitoring is complete, EC safeguard measures will remain in place, with the possibility of reduced controls over a reduced area as evidence of disease freedom is gathered.

12.4.2 The detailed arrangements for lifting zones and for continuing measures will be set out in an eradication plan submitted to and agreed by the Commission at the time of outbreak. If GB populations of feral pigs are too small to achieve the required level of testing, the UK will agree an alternative approach via the EC Standing Committee on Plants, Animals, Food and Feed (ScoPAFF) to gain disease freedom. The taking and killing of feral pigs may continue to be controlled for the duration of this surveillance to ensure that the remaining population does not move from the area and to ensure that all carcases are submitted for testing.
13 Glossary/Acronyms

Abattoirs - see slaughterhouse

AHVLA - Animal Health Veterinary Laboratories Agency, which will become part of the combined Animal and Plant Health Agency from 1 October 2014

AI - Artificial insemination

ASF - African Swine Fever

C&D - Cleansing and disinfection

CSF - Classical Swine Fever

CVO - Chief Veterinary Officer

EC/ EU - European Community/ European Union

Epidemiology - seeks to describe and explain the occurrence and distribution of disease by ensuring all possible explanations of the known facts are considered, and so can help identify what control measures are likely to work (or fail) under which circumstances

Feral pigs - free-ranging wild boar, feral domestic pigs or feral hybrid pigs

Fomites - any object or material capable of carrying infectious agents such as CSF virus. For example, vehicles, equipment, feedstuffs, clothing, footwear etc. May also include scavenging animals, vermin etc.

FBO - Food Business Operator

FPCZ - Feral Pig Control Zone - legally a term for the area declared as a result of disease in feral pigs

FPIZ - Feral Pig Investigation zone – declared where disease is suspected in feral pigs

FSA - Food Standards Agency

GB - Great Britain

IA - Infected area

IAPO - Import of Animals Pathogen Order

IP - Infected premises

MS - EU Member State/s

NE - Natural England

NEEG - National Emergency Epidemiological Group

NDCC - National Disease Control Centre

OIE - World Organisation for Animal Health

OV - FSA Official Veterinarian

PZ - Protection Zone
Relevant Minister - Secretary of State, Scottish Ministers, or Welsh Ministers

SCoPAFF - Standing Committee on Plants, Animals, Food and Feed

SAPO - Specified Animals Pathogen Order

Serological test - the testing of serum, which often refers to looking for antibodies, i.e. the animal’s response to infection

Slaughterhouse – place where animals are slaughtered with the intention of the animal product entering the human food chain. These are licensed by the Food Standards Agency or Local Authorities.

SP - Suspect premises

SZ - Surveillance zone

TCZ - Temporary Control Zone

UK - United Kingdom

VI - Veterinary Inspector

Virological test - the testing for the presence of viral material rather than the testing for evidence of the animal’s response to infection by that virus

VRA - Veterinary Risk Assessment
