This table is intended to provide valuations for partridges in release pens on a game farm. Release pens are generally large outdoor pens that provide limited shelter and protection to the immature pheasant prior to it being released into the wild. The birds are provided with food and water in the release pens, but are gradually encouraged out of the pen by the gamekeeper over a period of weeks. Valuation figures are provided from the 1st week of July, which is generally accepted as being the earliest that poults will be available. The latest date that birds might be recovered within release pens is the last week in September.

To value a flock, both the date of first placing in the release pens and the point at which the cull takes place needs to be ascertained. Thus the value of a bird placed during week commencing 8th July and a cull date of 29th July would be the amount shown in the highlighted cell. If the date the birds were placed and cull dates do not match exactly, the pro-rata valuation should be calculated.

In practice, birds do not spend more than a few weeks in the release pens, although they will return the pens overnight (especially if encouraged back by the gamekeeper). To allow for the possibility of birds being able to be culled for several weeks after initial placing the tables have been extended to cover the period up to the end of September.
